Many of the enigmas about the duckmole's structure and affinities are still unsolved, but there is no doubt that along with its neighbours it links mammals back to reptilian or even amphibian types. It need hardly be stated that it has no close connection with birds. Some of the most important structural characters may be briefly summarised: The bones of the skull fuse and are polished as in birds; the halves of the lower jaw do not unite in front, and have no swinging processes; the bones of the ear are in a primitive state. There are important technical peculiarities in the vertebrae, ribs, hip-girdle, &c. Epipubic bones, for instance, occur as in marsupials. The coroides are lacking the small membrane, and the breastbone is like that of the lizard and some other reptiles. The brain is smooth, and old fashioned in having a small corpus callosum and large anterior commissure. There is a common cloaca, receiving the rectum and the urino-genital canal. The heart in its structure is like that of birds. The ureters do not open into the neck of the bladder, but farther down into the short urino-genital canal. The left ovary is larger than the right, and the testes are abdominal. The oviducts have no 'fimbriated' upper ends, are separate throughout their course, open into the urino-genital passage, and thence into the cloaca. The vasa deferentia are open separately in the same way, and have only a temporary connection with the penis, which lies attached to the wall of the cloaca. The two milk-glands open on a flat bare patch of skin. In the duckmole, oviparous, there is of course no placenta. The eggs, like those of reptiles, undergo partial segmentation.

From the above it will be seen that the duckmole not only represents the lowest extent of mammalian evolution, but preserves, more markedly than the higher forms, traces of the far-off pedigree of the class.

See Echinida, Mammal, Marsupial; also Gould's Mammals of Australia (3 vols. 1854–63); Huxley's Vertebrates, and text-books of Comparative Anatomy; W. K. Parker's Mammalian Descent; Flower's Osteology of the Mammalia; Spencer, Nature, xxxi. (1884–85).

Orobanchaceae, or OROBANCHICAE, a natural order of parasitical herbs, generally with simple stems clothed with brown, purplish, yellow, or blue, but never green scales, instead of true leaves; terminating in a spike of flowers each in the axil of a scale or bract similar in colour and character to those of the stem. The species known considerably exceed one hundred in number, and are spread over the greater part of the globe, chiefly in temperate climates, but more abundant in the Old World than in the New. Eight species are natives of Britain, none of which belong to the genus Orobanche (Broomrapes), and one species to Lathrea (Toothwort). In Britain they are all rather rare or purely local plants. High medicinal virtues formerly were ascribed to some of the species, especially to Epipogium virginianum (see CANCER-ROOT), which are now discredited. With Phelippea tutae the Egyptians dye the ropes made of the palm Hyphaene thebaica black.

Orobus, a genus of plants of the natural order Leguminosae, sub-order Papilionacea, allied to Vetches, and sometimes called Bitter Vetch. The species are perennial herbaceous plants, chiefly natives of Europe. They afford good food for cattle. Two are natives of Britain, of which the most common is O. tuberosus, whose racemes of purple flowers often adorn heaths and bushy places, especially in hilly districts. Its roots are creeping and swell out into tubers at irregular intervals. The tubers have a sweet taste, resembling that of liquorice, and are sought after by children; they are also bruised and steeped in water in some parts of the Highlands of Scotland to make a fermented liquor, and a kind of liquor is made also by steeping them in whisky; they are well flavoured and nutritious when boiled or roasted, and are used in this way in the Highlands of Scotland, in Holland, Belgium, and other countries.

Orontes, the ancient name of a river in Syria, now called Nahr-el-Asi. It rises in the highest part of Cilicia, near Basilbèk, flows northward between the mountains of Libanus and Anti-Libanus, as far as the city of Antioch, and then westward to the Mediterranean Sea, through a total course of 147 miles. Its lower course is remarkably beautiful; its rocky banks are 300 feet high, and the windings of the river show them off to the greatest advantage. Myrtles, laurels, figs, wild vines, arbutoas, dwarf-oaks, and sycamores grow up the cliffs in picturesque irregularity. The country through which the river flows is in many parts richly cultivated.
Orosius, a Spanish presbyter and historian, was born at Tarragona, and flourished in the 5th century. He visited Augustine in 415, and presented to him his work written against the heresies of Priscillian and Origen. He went thence to Palestine to study under Jerome at Bethlehem. His chief work is entitled 'Histories Contra Priscilianos Libri viii., begins with the creation and goes down to 417 a.d. It is apologetic in design, intended as a complement to the great work of Augustine written to prove from historical evidence that the prevailing evils of the time were not due to Christian influence, but on the contrary, to the traditional practices of the Phrygian, and of the other nations, such as Orpheus the divine sort by coniidence semi situatc<l and vntcii/, the all lieiii}; during the time of Mipes's ISncon's Hesi«<l. universal Kent, favonril* sudden pity, heath, he gives us the History of the Argonauts, the Iliad of Homer, the Histories of Enrode, Jerone, and on Livy, Eutropius, Justin, Tacticus, and Suetonius; but the work is a trivial, inaccu- rate, miscellaneous medley of facts, although the style is elegant if not very, in Bacon's phrase. It was a favourite text-book of universal history during the middle ages, and had the honour of being translated into Anglo-Saxon by Alfred (ed. by Bosworth in 1831, and by II. Sweet from Lord Tolkien's 9th-century MS. 1853 et seq.). Some MSS. bear the puzzling title of Hornestara or Ormista, conjectured by some to be a corruption of Orosius's name Ormisarum, or perhaps Orosii mieriarum (muni<l) ratio.

The edicto princes appeared at Vienna in 1471; the best edition is that by C. Zangemelte in Corpus Script. Eccles. Latin. (Vienna, 1882). The edition of Haverseap (1504) is with vol. ix. of Prisca's Bib. (1778) and vol. xxxi. of Migne's Patrol. (1846); the history alone by Dr Mohol (Thom, 1877). An earlier English translation (1773) was reprinted in Bohn's 'Agricultor Liberati' (1833).

Oroviava, a town on the north coast of Teneriffe, one of the Canary Islands, is situated below the Peak, in one of the pleasantest districts in the world. Pop. 8293.

Orpheus, a Greek hero, a son of Apollo and the Muse Calliope, or of Eileus and Clio or Polyhymnia. His native country is Thrace, where many of the Orphic localities were pointed out as his birthplace. Apollo bestows upon him the lyre, which Hermes invented, and by its aid Orpheus moves men and beasts, the birds in the air, the fishes in the deep, the trees, and the rocks. He accompanies the Argonauts in their expedition, and the power of his music wards off all mischaps and disasters, rocking monsters to sleep and stopping cliffs in their downward rush. His wife, Eurydice, is bitten by a serpent and dies. Orpheus follows her into the infernal regions; and so powerful are his 'golden tones' that even stern Pluto and Proserpine are moved to pity, while Tantalus forgets his thirst, Ixion's wheel ceases to revolve, and the Danaiids stop in their wearisome task. He is allowed to take her back into the 'light of heaven,' but he must not look around while they ascend. Love or doubt, however, draws his eyes towards her, and she is lost to him for ever. His death is sudden and violent. According to some accounts, it is the thunderbolt of Zeus that cuts him off, because he reveals the divine mysteries; according to others, it is Dionysus, who, angry at his refusing to worship him, causes the Mænads to tear him to pieces, which pieces are collected and buried by the Muses in tearful pity at Leibethra, at the foot of Olympus, where a nightingale sings over his grave. Others, again, make the Thracian women divide his limbs between them, either from excessive madness of unrequited love, or to keep him from his absent husband away from them. The faint glimmer of historical truth hidden beneath these myths becomes clearer in those records which speak of Orpheus as a divine bard or priest in the service of Zagres, the Thracian Dionysus, and founder of the Mysteries (q.v.); as the first musician, the first inaugurator of the rites of expiation and of the Mantic art, the inventor of letters and the heroic metre; of everything, in fact, that was supposed to have contributed to the civilisation and initiation into a more humane worship of the deity among the primitive inhabitants of Thrace and all Greece. A kind of Orphic religious and poetical literature, the 'Hymns to the Muses,' supposed to be written by Orphne, the daughter of Zagres, and of Pythagoras; 'Myins, or Orpheus' descent into Hades; and other poetical productions by Zephyrus, Timocles, Nicias, Persius, Probicius, &c. Some poems belonging to the Orphic Cycle, of which, however, only names have survived in most instances, are Sacred Legends, ascribed to Cercopes; a Poem on Nature, called Physicus, probably by Brontimus; Bacchic, supposed to be written by Arigena, the daughter of Pythagoras; Myins, or Orpheus' descent into Hades; and other poetical productions by Zephyrus, Timocles, Nicias, Persius, Probicius, &c. The hymns have repeatedly been translated.

See the editions of the Orphica by Hermann (1805) and Abel (1885); Lohmeyer's 4th ed. (1829); and Gerhard, Orphoiou et die Orphoton (1861).

Orpiment. See Arsenic.

Orpine, a kind of Scolium (q.v.).

Orpington, a village of Kent, England, 12 miles by rail SE. of London, where Ruskin's books began to be published in 1873 (see E. T. Cook, Studies in Ruskin, 1890). Pop. 3000.

Orrey, a machine constructed for the purpose of exhibiting the motions of the planets round the sun, and of the satellites round their primaries, which was in high repute during the 16th and
beginning of the 19th centuries, though now regarded as a mere toy. Made by Bowley in 1715 at the expense of Charles Boyle (q.v.), Earl of Orrery, it was a combination of the optical principles of the 16th century with other machines which showed the motions of the earth, moon, and planetary satellites. Though the construction of a machine which would exhibit accurately the motions, disturbed by the force of the tides, is impossible, yet an error is in some degree useful as giving a general notion of the way in which the planetary motions are performed. As it was a favourite machine at one time, a description of it may not be uninteresting. A number of iron tubes equal in number to the planets, and of different dimensions, are placed one within the other; their lengths being arranged so that the innermost tube projects at both ends beyond the one next to it, that one similarly projects beyond the other, and so on. At one end of each tube a rod is fixed at right angles, and a ball or lump attached to its end; the lengths of the rods being proportional (or at least supposed to be so) to the radii of the planetary orbits. The other ends of the tubes form the axes of toothed wheels, which are connected, either directly or by means of combinations of smaller wheels, by a variety of gear wheels. The revolutions of the wheels are so adjusted that the velocity of revolution of the rods is proportional to the times of revolution of the planets. On turning the wheel the whole apparatus is set in motion, and the ball or lump (representing the planets) revolve round the centre, which is fixed lump (representing the sun), at different distances, and with varying velocities.

**Orris-root** (probably a corruption of *Iris* Root), the root-stick (*rhizome*) of certain species of *Iris* (q.v.), natives of the south of Europe, belonging to the division of the genus having bearded flowers, sword-shaped leaves, and scapestaller than the leaves—viz. *I. florentina*, a species with white flowers; *I. pallida*, which has pale yellow flowers; and *I. germanica*, which has deep purple flowers. The flowers of all these species are fragrant. *I. germanica* extends farther north than the other species, and in many species are of a more acrid odor. Orris-root was formerly used in many medicinal preparations as a stimulant, but is now almost entirely disused. It is sometimes chewed to sweeten an offensive breath. Its chief use is in perfumery. It is used as a diuretic, and made into a的脸or in drying. Hair and tooth powders, and oils, are often scented with it. A tincture of it also is used as a scent, and is often sold as *Essence of Violets*.

**Oryx**. See **D’Orsay**.

**Orsini, Felice**, conspirator, was born in December 1819, at Melbola, in the States of the Church, and studied at Bologna. He belonged to a branch of a noble family, long famous as supporters of the Guelph party, which produced famous scholars, soldiers, and churchmen (including two popes, Nicholas III. and Benedict XII.). Felice, the son of a conspirator, was early initiated into secret societies, and in 1844 was sentenced at Rome to the galleys for life. The amnesty of Pius IX. (1846) released him from bondage, but he was taken by the Prefect of Rome and imprisoned for participation in political plots. When the revolution of 1848 broke out Orsini was elected a deputy to the Roman Constituent Assembly, and, invested with extraordinary powers, was sent to Amiens and Arras to suppress brigandage. He signalled himself by the violence with which he executed his commission. He also took part in the defence of Rome and Venice; agitated in Genoa and the duchy of Modena; and in 1853 was shipped by the Sardinian government to England, where he formed close relations with Mazzini. Furnished with money by the leaders of the revolutionary party, he appeared at Paris in 1854, and afterwards at Trieste, Vienna, everywhere agitating in the interest of insurrection. Until at last he was arrested at Hermannstadt, and confined in the fortress of Mantua. In 1856 he succeeded in making his escape, and found refuge in England, where he supported himself by public lecturing, and also wrote *Dungeons in Italy* (1856). Towards the end of 1857 he repaired to Paris with the intention of assassinating Napoleon I., whom he reckoned the great obstacle to the progress of revolution in Italy. His associates in this diabolical design were persons named Pieri, Rugio, and Gomez. They took up their station in a house close by the Opera, and on the evening of the 14th January 1858, just as the carriage containing the emperor and empress was drawing up, they threw three bombs under it. An explosion took place, and 10 persons were killed, 126 wounded, but Napoleon and the empress remained unhurt. The assassins were arrested, tried, and sentenced; Orsini, Pieri, Rugio, and Rugio, to capital punishment, Gomez to penal servitude for life. Rugio’s life was saved at the intercession of the empress, but Pieri and Orsini were guillotoncd on 15th March. See *Memoirs of Felice Orsini* (Eng. trans. Edin. 1857); his Letters (2 vols. Milan, 1861); and a work by Montazio (1892).

**Osrova**, the name of two towns on the Danube over against the Iron Gates. Old **Orova**, a Hungarian place, is 478 miles by rail S.E. of Vienna, and is a station for the Danube steamer. Pop. 3381. — **New Orova**, on the Servian side, is a fortified town held by Austria (since 1878), who also were masters of it between 1716 and 1738; the Turks held it both before 1716 and after 1738. In 1890-96 a costly canal and other works were made for facilitating navigation at the rocky bend called the Iron Gates (see **DANUBE**).

**Oregal, Cape**, the north-west extremity of Spain (q.v.), in Galicia.

**Ortelius**, the Latin form of the name of **Abraham Ortel**, or Ortel, who, born of German parents in 1527 at Antwerp, where he also died in 1598, published the earliest atlas under the title *Theatrum Orbis Terrarum* (1570); a critical work on ancient geography. See *Ortelius* (1578), re-issued, greatly improved, as *Theatrum Geographiarum* (1590); and other geographical works. He was also a frequent traveller to England, Ireland (1577), and Italy, and the countries between.

**Orthez**, a town in the French department of Basses-Pyrénées, on the right bank of the Gave de Pau, 41 miles by rail E. of Bayonne. The ‘Tour de Moncade’ (1240), the stately castle of the counts of Foix (q.v.), which Froissart visited in 1388, was reduced to a ruin by Richelieu. Near Orthez Wellington gained a decisive victory over Suet, 27th February (1814). See *Pop.* 4575.

**Orthoceras**, a large genus of common fossil Cephalopods. The shells are quite straight, but a gradual series of forms lead on to the Nautilus type. Some species of orthocerases were gigantic; thus, *O. Titan* in its fossil state is said to have weighed some tons.

**Orthoclase-porphyry**, a crystalline igneous rock, of variable colour, but generally reddish. It is fine-grained and has a variety of texture. The ground-mass is felspathic, and micro- or cryptocrystalline; now and again it shows a little glassy or devitrified matter. Scattered through this ground-mass are microscopic crystals of orthoclase, and usually some hornblende and biotite in small
ORTHOCLASSE-ROCKS

OsaKA

granules, crystals, and scales. The rock is met with amongst Palaeozoic strata, both as contemporaneous lava-flows and as intrusive masses. See also FELSPLAH, and IGNEOUS ROCKS.

Orthoclase-rocks. See PETROGRAPHY.

Orthodoxy (Gr. orthos, 'right,' and doxai, 'an opinion'), a name given by theologians to religious opinions in agreement with Scripture and historical tradition, or rather with the interpretation of these entertained by the particular church to which they themselves happen to belong. While it is true that the great cardinal and essential points of Christian dogma have been preserved by all sections of the Church of Christ, the gravest divergences have also arisen, alike in doctrine and practice, each fortified by an assumed infallible interpretation of the letter of Scripture, where it is of historical descent in the usage of the church. — The antithesis of orthodoxy is heterodoxy (heteros, 'other'—i.e. 'wrong,' and doxai, 'opinion').

Orthoepy (Gr. orthos, 'right,' epos, 'a word'), a branch of grammar that treats of the correct pronunciation of the words of a language.

Orthography. See SPELLING.

Orthoptera (Gr., 'straight-winged'), an order of insects (q.v.).

Ortolan (Emberiza hortulana), a species of Bunting (q.v.) of the Finch family Fringillidae. The adult male is about six inches long; has the head, neck, and upper breast slate-gray suffused with yellow; bill reddish brown; chin, throat, and feathers round the eye yellow, with a narrow band of greenish gray descendent from a little in front of the angle of the mouth; back, wing-coverts and secondaries fulvous brown with dark stripes; rump reddish brown. The plumage of the female is paler in colour. The ortolan in its summer migrations ranges as far north as the Arctic Circle in Scandinavia. In the south of Europe, where it is found in great numbers, and in the north of Africa, it sometimes breeds, but is but a summer visitor. In winter it migrates as far south as to Abyssinia and North-western India, but its true winter quarters have not yet been accurately ascertained. Though more or less abundant in certain localities on the Continent, it is rare in Britain, and many of the specimens captured have no doubt escaped from captivity, considering the large quantities imported alive from Holland and Belgium. It frequents bushy places, and builds its nest of dry grass among the ground and generally in the open fields, though sometimes among herbage or under low bushes. It lays from four to six eggs, which vary in colour from very pale-blush white to salmon colour, spotted with rich purple brown, with underlyingspots of pale violet, not streaked as is usual with other banting. The note of the male is rather metallic, and his song at times is incessant and very monotonous. The food consists of beetles and other insects and seeds. Large numbers of ortolans are netted during their migrations, and confined in dark or dimly-litged rooms, where they are fattened upon oats and millet until ready for the table. Their flesh is considered a great delicacy.

Orton, Arthur. See TICHBORNE.

Ortona, a town of Italy, on the Adriatic, 104 miles by rail E. of Ancona. It has a cathedral and a recently improved harbour. Pop. 6366.

Oryx. See VIRGINIAN QUAIL.

Oroho, capital of the department of Ororo, in Bolivia, stands on a saline plain 11,900 feet above the sea, near the salt lake of Uallaghas, and possesses mines of silver, gold, and tin. Founded in 1590, it had 70,000 inhabitants in 1630, but now, though connected by rail with Antofagasta, has only 13,500. The department, bordering on Peru, has an area of 21,000 sq. m., and a pop. of 111,400. The soil is saline, but the mineral wealth is great.

Orvieto, a city in the Italian province of Perugia, 78 miles NNW. of Rome, crowns an isolated tufo rock, which rises 765 feet above the river Paglia, and 1327 above sea-level. The cruciform cathedral (1290-1580), one of the most beautiful and highly decorated specimens of Italian architecture, is built of black and white marble, and measures 295 feet by 109. The façade is unsurpassed in richness of material, and in the beauty of its mosaics, sculptures, and elaborate ornamentation. The interior also is magnificently decorated with sculpture and mosaics, with paintings by Signorelli, Fra Angelico, &c. The bishop's palace of St. Patrick's Well (1257-40), with its 250 steps, are also noteworthy. Pop. 7504. Orvieto, called in the 7th century A.D. Urbis VetVs—of which its present name is a corruption—has by some been supposed to be the site of the city of the ancient Volatii. In the middle ages it gave shelter to thirty-two popes. See works by Groner (Leip. 1868), Berir (Lond. 1884), and Pizocolonini (Siena, 1885).

Orwell. See IPSWICH.

Oryx, an old name given to several large and heavy African antelopes, with very long, slightly curved horns. One species (Hippotragus leucongens) frequents the deserts of Central Africa, and once extended farther north, as is shown by the frequency of its apparently ' unicorn' figure on ancient monuments. Another form (H. ceposus) is found in Khataria. But the name oryx has been used somewhat widely. See ANTELOPES.

Orzya. See RICE.

Osage Orange (Maclura aurantiun), a tree of the natural order Moraceae, a native of North America. It attains a height varying, according to soil and situation, from 20 to 60 feet. It is of the same genus with Fustic (q.v.), and its wood, which is bright yellow, probably might be used for dying. The wood is fine-grained and very elastic, and takes a high polish; it is much used for fence-posts, sleepers, paving-blocks, &c. The tree is largely employed in America, especially in the west, as a hedge-plant; it has also been introduced into Britain for that purpose, but has not met with general appreciation. Its fruit is about the size of a large orange, has a terebrated surface of a golden colour, and is filled internally with radiating, somewhat woody fibres, and with a yellow milky juice, the odor of which is generally disliked, so that the fruit, although not wholesome, is seldom eaten.

Osages, a tribe of American Indians, of the Dakota stock, formerly very troublesome, but now settled in the north of Indian Territory, with Quaker teachers. They number about 2000.

Osaka, or OZAKA, an important city of central Japan, situated at the head of the Gulf of the same name, and at the mouth of the YodE River, which issues from Lake Biwa. The city covers an area of
about 8 sq. m., and is intersected with enwalls. Its
fine castle, the stones of whose walls are of astonishing
size, was burnt by Hideyoshi’s armies in 1593, and the
palace, built after the model in its circumference
and destroyed in 1808, was perhaps the most magni-
cificent structure in Japan. Osaka is the great
commercial centre of the empire, and the head-
quarters of the rice and tea trade. Its port does
not admit the entrance of large vessels, and is the
most impenetrable Everglades, with two or three
hundred followers, he fought for nearly two years
with great energy and skill the superior numbers sent
against him. He was taken prisoner at last, in
October 1873, by an English detachment, while holding
a conference under a flag of truce—an act of
inexcusable treachery, though represented as one of
reparation—and confined in Fort Mon литератур before
his death, 30th January 1838. Mayne Reid, in
Oscoda, has woven the story into a romance.

Oscott, a Roman Catholic college, near Bir-
ingham, which claims to be the centre of the
Roman Catholic movement in England. The name
(or Aescott, as it is spelt in Camden’s Britannia)
is first met with towards the close of the 17th century
as the seat of a Catholic mission, which continued
to be served by different priests till in 1732 it was
presented to the see of Lichfield and考核ed to
the care of the Seminary, and the study of the
laws, classics, science, and mathematics, to meet
the requirements of the London University B.A. Exam.
After this the course consists of two years of
mental philosophy and three and a half of theology
and kindred subjects. The staff includes a rector,
vice-rector, and eight professors, and the seminary
is open to students from any British diocese.

O'Shaughnessy, Arthur, minor poet, was
born in London, 14th March 1846. He was em-
ployed in the natural history division of the British
Museum, married a daughter of Dr Westland
Martin, was made poet in 1875, and followed to
the grave on 31st January 1881. During his brief
life he published Epic of Women (1871), The Lords
of France (1872), and Music and Moonlight (1874);
and soon after his death appeared Songs of a
Worker (1881). As a poet he is somewhat diffuse,
over-gorged with ideas, but thoughtful in his con-
cerning in his admiration for modern French
models; yet he reveals imagination, passion, ten-
derness, melody, and a mastery of lyrical forms.

Oshkosh, capital of Winnebago county, Wis-
sconsin, on both sides of the Fox River, at its
entrance to Lake Winnebago, 80 miles by rail
NW. of Milwaukee. The lake (30 miles by 12),
with the Fox and Wisconsin rivers, which are
connected by a canal, forms a water-route between
Lakes Michigan and Superior. The city extends
along the lake for 4 miles, and contains a number
of handsome buildings. It carries on a great trade
in lumber, and contains fifteen sawmills, extensive
black and sash factories, and large manufactories
of furniture, matches, carriages, and soap, besides
pork-packing establishments. It is the seat of
a state normal school, and close by is a state
lunatic asylum. Oshkosh was incorporated in 1833,
and burned down in 1889; it was again partially
destroyed by fire in 1874 and 1875, and in 1885
a cyclone overwhelmed part of the suburbs.
Pop. (1880) 15,743; (1890) 22,836; (1900) 25,284.

Ostlander, Andreas, German reformer,
was born on 15th December 1498, at Gunzenhausen,
near Nuremberg, a town of the principality of the
original German Heiligmann or Rosemann.
Educated at Ingolstadt, he declared himself
an adherent of Luther, and became a preacher at
Nuremberg (1522), persuaded that city to declare
itself Lutheran, took part in the conference at
Marburg (1529), and was present at the diet of

OSBORN

OSIANDER

631
Augsburg (1530), and at the signing of the Schmal-
kald articles (1637). In 1548 he was deprived of
his office as preacher because he refused to agree
with the Augsburg Interim; but was immediately
afterwards invited by Albert, Duke of Prussia,
to become professor of Theology in the newly-es
established university of Koenigsberg. He was later
settled there when he became entangled in a theo-
logical strife that was greatly embittered by his
vehement and arrogant temper. In a treatise, De
Loge et Evangelio, Osianlder asserted that the
righteousness by which sinners are justified is not
to be conceived as a mere juridical or impotent
active act on the part of God, but as something
inward and subjective, springing in a mystical way
from the union of Christ with man. The most
notable of his opponents was Martin Chemnitz
(q.v.). Osianlder’s death in the midst of this fierce
political war, on 17th October 1552, did not check
it; the battle was continued by his followers,
called Osianldists, and led by his son-in-law Funk,
who was executed for high treason in 1566, and
the entire party was banished from Prussia in 1567.
See Lives by Wilken (1844), Meiler (1870), and
Hase (1879). Osianlder’s son-in-law Wilken (1584–1604)
and his son Lucas (1571–1638) won reputations as
theologians of note.

**Osier**, the popular name of those species of
Willow (q.v.) which are used chiefly for basket-
making and other wickerwork. They are of low
bushy growth, few of them over becoming trees,
their branches long and slender; and they are the
more valuable in proportion to the length, slender-
ness, suppleness, and turgidity of their branches.

The Common Osier (*Salix viminalis*), a common
native of wet alluvial grounds in Britain and many
parts of Europe, is one of those which sometimes
become trees, although when cultivated for basket-
making it is not permitted to do so. It is often planted
to prevent the banks of rivers from being washed away. Its
branches are used for making hoops and coarse baskets.

There are several varieties in cultivation,
not easily distinguished except by a very practiced eye,
but much more useful than the original or wild kind, which
are used to break, and therefore of little value. More suit-
able for the finer kinds of basket-making are *Salix
forbyana*, sometimes called the fine Basket Osier,
and *S. rubra*, known near London as the Green-
leaved Osier or Ormard; *S. tristis*, a triandrous species,
known to English osier-cultivators and basket-
makers as the Spangler Rod; whilst *S. vitellina*, a pentandrous species, sometimes becom-
ing a tree, is the Golden Osier or Golden Willow,
remarkable for the bright-yellow colour of its
impressions, and because for their pliancy and tough-
ness. There are other species, not natives of
Britain, which also are valuable.

Osiers are very extensively cultivated in Holland,
Belgium, and France, on alluvial soils, especially
near the mouths of rivers; and from these countries
great quantities of 'rods' are exported into Britain.
They are cultivated also to a considerable extent
in some parts of England, particularly on the banks
of the Thames and the Severn, and in the level
districts of Cambridgeshire, Huntingdonshire, &c.
Islets in the Thames and other rivers, entirely
planted with Osiers, is called Osier holls. Osiers
grow particularly well on grounds bordering rivers.
Much depends on the closeness of planting
of osier grounds; as when space is too abundant
the shoots of many of the kinds do not grow up
so long, slender, and unbranched as is desirable.
Osiers are also cultivated by Osier-cultivators,
when they wish Osiers for the finest kinds of osier-
work or ground Osiers, they plant the shoots into little
bits with a bud or eye in each, and plant these pretty
close together, so as to obtain weak but fine shoots;
but generally cuttings of 15 or 16 inches in length are used,
and of tolerably thick branches, and these are placed in
rows from 18 inches to 2 feet apart, and at dis-
tances of 15 to 18 inches in the row. Osier planta-
tions in light soils continue productive for fifteen
or twenty years, and much longer in rich alluvial
soils. Osiers succeed best in rich soils, but not in
clays. No cultivation is required after planting;
but the shoots are cut once a year, at any time
between the fall of the leaf and the rising of the
sap in spring. After cutting they are sorted,
and those intended for brown baskeits are carefully
dried and stacked, care being taken that they do
not heat, to which they are liable, like hay, and by
which they would be rotted and rendered worthless.
The stakes must be protected carefully from
rain. The osiers intended for white baskets cannot
at once be peeled, but, after being sorted, they are
placed upright in wide shallow trenches, in which
there is water to the depth of about four inches, or
in rivulets, being kept some time in bright posi-
tion by posts and rails; and thus they remain till
they begin to bud and blossom in spring, which
they do as if they remained on the parent plant,
sending forth small roots at the same time into
the water. They are then, in ordinary seasons, easily
peeled by drawing them through an instrument
called a break; but in cold springs it is sometimes
necessary to lay them for a while under a quantity of
litter. After being peeled, they are stacked,
preparatory to sale. See Basket.

**Osiris**, greatest of Egyptian gods, is the son of
Set (the Earth—here the father) and Nut (Heaven—
the mother). He was said to have been begotten
by his father, and judges the dead in the nether
world. The myth is generally interpreted by taking
Osiris for the Sun, Set for darkness, Osiris
had by Nephthys another son Anubis (i.e.
Duck), who is said to have swallowed his
father. Osiris has also been identified with the god Isis,
with the Moon, with the Nile, and with the annual
sun-period or summer (as against the daily appear-
ing sun). For further discussion of the myth, see
Isis, and works quoted there; also Wiedemann,
*Die Religion der Alten Aegypter* (1890).

**OskaLoosa**, capital of Mahaska county, Iowa,
104 miles NW of Davenport. It possesses mines of bituminous coal, and manufactures
flour, woolens, boilers, electric appliances, &c.
Here are Penn College (Quaker) and two others.
Pop. (1880) 6388; (1900) 9392.

**Osmium** (sym. Os; atom. wt. 191) is a metal
which occurs in association with platinum in the
form of an osmium-iridium alloy. It may be
obtained with metallic character in a number of
sorts which yield it either as a black amorphous
powder or in hard bluish-white crystals. It is the
least fusible of all the metals, the oxides of the
metal very volatile, but not fusing. It is the heaviest
Osmose, the interdiffusion of two liquids through a septum, usually of bladder or of parchment paper. If a bottle, filled with one liquid, be closed by parchment paper, and then completely immersed in a vessel containing another liquid, an increase or decrease of the contents of the bottle will occur according as the liquid contained in the bottle passes out through the septum less quickly or more quickly than the other liquid passes inwards. When the contents are increased the phenomenon has been called endosmosis; when they decrease it has been termed exosmosis. The distinction is obviously not a scientific one; for a reversal of the positions of the liquids will cause a reversal of the osmotic process, so that the process which was formerly denominated exosmosis must now be called endosmosis, and vice versa. The phenomenon is one of extreme importance, for it is constantly taking place in living bodies—both animal and vegetable.

Nollet was the first to record the occurrence of osmosis. He heated a vessel, filled with alcohol and closed with a piece of bladder, inside a larger vessel which was filled with water. The rapid entry of the water almost burst the bladder; and the opposite effect took place when the water was placed inside the inner vessel and the alcohol was placed outside it. Nollet did not pursue his observations any further. Dutrochet first made careful investigations into the subject, which has since received numerous practical applications—notably in the method of dialysis, which is due to Graham. The phenomenon consists merely in the interdiffusion of two liquids complicated by the mutual molecular actions which take place between the liquids and the material of the membranes. The rate of interdiffusion depends greatly upon the nature of the membrane; sometimes the direction of the osmose is altered when the membrane is altered. The action being essentially molecular, we can readily understand how sap may be raised to great heights in plants and trees against the action of gravity; for the molecular forces in a drop of water (say) are sufficiently powerful to hold the passage of water against the gravitational attraction of the whole earth.

A process which is analogous to osmosis occurs in the interdiffusion of two liquids through an intervening liquid layer. The difference between the rate of diffusion of colloids and crystalloids is even more marked when the substances are separated by parchment paper or animal membrane than when they diffuse directly into each other.

Osmunda. See Royal Fern.

Osnabrück, a town in the Prussian province of Hanover, in the fertile valley of the Hase, 75 miles by rail SSW. of Bremen and 70 WSW. of Hanover. Its great Catholic cathedral, in the Transition style of the first half of the 13th century, is rich in relics and monuments; and the town-hall (1490-1512) contains portraits of all the plenipotentiaries who here on 24th October 1618 signed the peace of Westphalia. By that treaty the bishopric of Osnabrück, founded by Charlemagne about 810, was to be occupied alternately by a Catholic prelate and a Protestant secular prince of the House of Brunswick-Lüneburg. After having last been held by Frederick, Duke of York, the district of Osnabrück came in 1802 to Hanover, and the chapter was dissolved, until the re-establishment of the bishopric in 1837. Osnabrück has important iron and steel works, and manufactures of railway plant, agricultural machinery, gas-meters, paper, tobacco, &c. Dating from 722, it suffered much in the Thirty Years' War, but recovered, thanks to its linen industry, during the 18th century. The name Osnabrück is derived from Osuna, a saint.

Osprey (Pandion haliaetus). A Fish-Hawk, a not infrequent autumnal visitor to British shores, estuaries, and lochs, where it feeds exclusively on fish. It has been known to breed in England, and several eyries still remain in Scotland. But its distribution is almost cosmopolitan, for it occurs on all the continents, especially where fish are common and men rare. The male bird is 22 inches in length; the female 24. 'The adult male has the head and neck white, streaked with brown; upper plumage under, with a purplish tinge; under parts white, with a band of brown spots across the breast; cere, legs, and toes greenish blue.' The female has more brown on the breast. A large nest of sticks and turf, with a small moss-lined cavity for the eggs, is built on a tree or rock. The eggs (two or three) are laid in April, May, and have a 'ground colour of white or buff, with chestnut or claret blotches, and blurs of purplish grey.' In North America the osprey is gregarious. It never preys on other Birds, and is not dreaded by them. It is, indeed, of a pacific and timorous disposition, and readily abandons its prey to the White-headed Eagle. In the days of falconry it was sometimes trained and used for catching fish. See Howard Saunders, British Birds.
Ossian, the great heroic poet of the Gaels. In form the name is a diminutive—Oisín, Oisin, the little or dear. In Gaelic story Ossian was the son of Finn MacCumhaill, a celebrated hero who flourished towards the close of the 1st century B.C. Finn gathered about him a band of warriors like himself, who were collectively termed the Feinn. The adventures and exploits of these heroes, and especially of the principal figures in the group—of Finn himself, magnificent and wise; of his grandson Oscar, chivalrous and daring; of his nephew Diarmid, handsome and brave; of his rival Goll, the one-eyed; and Conán, the villain of the band—their jollities, dissensions, and final overthrow constitute the literature of the Feinn. The story goes that Ossian was carried away by his fairy guardians, Óg and Ogê, ‘the young,’ from whence he returned betimes; and now old, blind, and alone, ‘Ossian after the Feinn,’ he told the story of the heroes to St Patrick.

The legends of the Feinn are but a fragment of the heroic literature of the Gael, and in the oldest MSS. the deeds of Finn and his companions occupy but little space. There were two earlier cycles. The first of these extended from unknown antiquity until the settlement of the Gaels in Ireland. The legends of this period preserve traditions of the old divinities of the race, notably the Tatha dh’Aisneach, under the guise of earlier colonists whom the Gaels conquered and displaced. Several tales of this cycle are preserved, among which the Fate of the Children of Tuireann and the Fate of the Children of Lir are the best known. The second, and by far the richest, epoch in Gaelic romance is that of Cuchulain, Conall Cernach, Fergus, and the Sons of Uisneach. The date is about the commencement of the Christian era, when Conchobar MacNessa ruled Ulster and Queen Meave ruled Connacht. The great literary product of this period is the Cattle Spoil of Conaille, the Life of the Gop, Aengus, a long poem recounting the death of the Sons of Uisneach and suicide of the Lady Deirdre, the Darthala of James Macpherson. Eventually the legends of the Feinn partly absorbed and totally eclipsed the earlier traditions; so that Ossianic literature is now but another name for the heroic literature of the Gael.

These traditions have come down from the misty past in tale and ballad. They were early reduced to writing, and as time goes on we observe great development in incident and detail. In ballads,, a *booklet* of Lewis in 1550 A.D. Osísean is represented as old and blind, surviving father and son. A 15th-century MS. recounts the boyish exploits of Finn. As we come down, the volume of tradition gets fuller, while cycles tend to become confused. The leader of the Feinn is at one time a god, at others a hero, a king, a giant, but usually a great warrior, as wise as brave. In the book of the Don Caw his mother is Muirn 'of the Fair Neck'; in later traditions we hear of Finn as the son of a sister of Cuchulain; at another time a Scandinavian princess is his mother. But the name Finn is preserved practically unchanged. A Gaelic tale is of a distinct type—narrative prose with verse interspersed. Gaelic poetry, older and later, is ever rhymed lyric verse.

To the majority of people Ossian is known through the publications of James Macpherson (q.v.); his translations of Fingal, an epic poem, in six books; Teumars, another epic, in eight books; with a number of shorter pieces, epic and dramatic—all purporting to be translations of poems composed by Ossian, the son of Finn. 'The translation,' Dr Blair is said to say in the preface to the *Remains* published in 1769, 'is extremely literal.' These publications, in the opinion of the most competent judges, possessed great literary merit. They brought wealth and fame to the author, and before the end of the century a translation of them was published in London. James Macpherson gathered about him a band of warriors like himself, who were collectively termed the *Feinn*. The adventures and exploits of these heroes, and especially of the principal figures in the group—of Finn himself, magnificent and wise; of his grandson Oscar, chivalrous and daring; of his nephew Diarmid, handsome and brave; of his rival Goll, the one-eyed; and Conán, the villain of the band—their jollities, dissensions, and final overthrow constitute the literature of the Feinn. The story goes that Ossian was carried away by his fairy guardians, Óg and Ogê, 'the young,' from whence he returned betimes; and now old, blind, and alone, 'Ossian after the Feinn,' he told the story of the heroes to St Patrick. OSSIFICATION

OSTEND

people. But there he part company with it. Gaelic literature supplies material for epics and dramas; but the only precious literary forms, were unknown to the people. The dim and shadowy characters of Macpherson are in sharp contrast to the clear-cut features of the Gaelic heroes. Barely does this author make a definite statement of fact; but when he does, as when, for instance, he states that it was a noble箭, he blunders hopelessly. Macpherson is the most vague and abstract of writers; Gaelic poets are wornisome in detail, and revel in the concrete. In the opening of Book iii, of Cathloda, the author inquires regarding the origin and issue of his narrator, who is his faithful and beloved servant. 

Macpherson was not a Gaelic scholar, and the fact is considered conclusive proof of his inability to compose the Gaelic text of Osian. The only Gaelic printed in the author's lifetime was Temora, Book vii. Osian was but in his frequent use of the languages of Europe before he appeared in his own. And when at length the great edition of 1807 did appear, there were Gaelic texts for only one-half of the poems, and for about three-fourths of the more fashionable of his chief literary English literary five years previously. For the others, no 'original,' ancient or modern, has ever yet been found. And it must be allowed that this truncated Osian does not show to advantage in his native garb. The Gaelic-speaking people have never known him, and no Gaelic text has been published by Macpherson to prove him writing to Macpherson's day. The diction is essentially modern. The loan-words are numerous, several of them borrowed from English. The idioms and constructions are colourless, and show traces of the transplanting rather of his own and the turn of phrase characteristic of native authors. The so-called blank verse in which the poems are written is unknown to Gaelic poetry. The archaic orthography of the seventh book of Temora was added by Dr. Clerk of Kilmaulie as proof of the antiquity of the poems. Osian was but in his frequent use of the tenes (p. 6), instead of the medius (q. d. b.), Macpherson merely followed Alexander Macdonald, who published his own poems twelve years previously. By the same gifted man he was led into taking great delight in the use of a cartilaginous, uncivilized noun, contrary to invariable Gaelic usage, which has the sun as well as the moon of the feminine gender.

The truth seems to be that these so-called translations were essentially the compositions of James Macpherson, and that the Gaelic texts were prepared with or without aid from his friends, but how and when we do not now know. The only man who could explain things died and made no sign. One regrettable consequence of this famous epistle in the history of Gaelic literature still remains. To many persons the discrediting rather of James Macpherson means the blotting out of existence of an extensive and interesting literature—the heroic literature of the Gaeal.

See the Poems of Osian (1762-63); Broads' Reliques of Gaelic Poetry (1789); Osian (1807) ; Transactions of the Osian Society of Dublin (6 vols.); Poetical Works of the United Highlands (1806-62); Dean of Lis- more's Book (1861); Clerk's Osian (1870); Leuchabh na Pheine (1873); Folk and Hero Tales from Argyllshire (1880); 12 Texte der deutschen Alten, vol. iii.; Academy, February 1891; William Sharp's Introduction to the century edition of Osian (1898); and books noted at Macpherson (James).

OSSIFICATION is the formation of bone. Most human bones are first represented by cartilage, which, by a complicated series of changes, becomes transformed into bone. The bones of the vault of the cranium and the face, part of the clavicle, and the sesamoid bones occurring in tendons, on the other hand, are developed from fibrous tissue, without passing through a cartilaginous stage, and are distinguished as membrane-bones. In the larger bones of the limbs at least three centres of ossification are found, one in the shaft, and one at each extremity. Growth of the bone takes place mainly at this last centre, which, when long remain cartilaginous. Bony union becomes complete in each situation at a tolerably definite age (in some not till about twenty-five; see Bone). True Ossification sometimes occurs as a morbid process; but in many cases the term is incorrectly used (especially in the case of blood-vessels—under ARTERIES) to designate a hard calcareous deposit, better called calcification, or calcareous degeneration, in which the characteristic microscopic appearances of true bone are absent. In one sense the osseous tissue that is formed in generation of destroyed or fractured bones (see Fractures) may be regarded as due to a morbid, although a restorative action. Hypertrophy of bone is by no means rare, being sometimes local, forming a protuberance on the external surface, in which case it is called a periosteal bony growth, often extending over the whole bone or over several bones, giving rise to the condition known as hyperostosis. Again, true osseous tissue occasionally occurs in parts in which, in the normal condition, no bone existed, as in the dura mater, in the so-called pterylar cartilages (as those of the larynx, ribs, &c.), in the tendons of certain muscles, and in some forms of tumours. The peculiar causes of the ossiferous formations which are unconnected with bone are not known.

Rossi. See Fuller (Sarah Margaret).

Ossory, a diocese of the Roman Catholic Church of Ireland, embraces the county of Kilkenny and parts of Kilkenny. The Queen's native and bishop has his cathedral at Kilkenny. There is an Ossory parliamentary division in Queen's County.

Ostade, Adrian, painter and engraver, was born at Haarlem in December 1610, and in that city he died, 27th April 1683. His teacher was Frans Hals. County dancing greens, farm-servants, stables, the interiors of rustic houses and houses, and beer-shops are the places which he loves to paint; and his persons are for the most part coarse peasants, ugly, sordid, dirty, ragged, Yigour and close observation, with skilful management of lights, are the distinguishing marks of his manner and his st源于; and humour and poetic appreciation are not frequently present. About 1639 he fell under the influence of Rembrandt's style. He was a prolific painter, and his works are to be found in the museums and collections of the Netherlands, Germany, Austria, Russia, France, and England. See a work by Bode (Vienna, 1881).—Isaac Ostade, brother of Adrian, also a painter, was born at Haarlem in 1621, and died at Amsterdam in 1649. Until 1644 he worked in the style of his brother, but then struck out a path for himself, and excelled in realistic scenes, with the landscapes, village street life, and similar subjects.

Ostashkoff, a town of Russia, stands on the south-east of Lake Seliger, 107 miles W. by N. of Tver. It is one of the chief centres in Russia for the making of boots and shoes. Pop. 9903.

Ostend, a fashionable watering-place, the Belgian province of West Flanders, on the Gessian Ocean, 77 miles by rail WNW. of Brussels. Its Digue, or sea-wall, 3 miles long, 40 feet high, and 35 yards broad, forms a favourite promenade, as also do the two Estacades, or wooden piers, projecting on both sides of the harbour's entrance. Two spacious floating basins for the Dover mail
OSTENTORY

The Ostentory was a ceremonial vestment of the Roman Church, worn by the Bishop of Rome and other high Church dignitaries. It was made of brocade, embroidered with gold and silver thread, and was supported by a long, pointed cincture.

OSTERODE

While not a town mentioned in the text, Osterode is a city in Germany, known for its many historical buildings and its association with Martin Luther, who preached here in 1522.

OSTRICH

Ostriches are flightless birds native to Africa, known for their long necks and large, wingless bodies. They are the largest living birds, with some species reaching heights of over 9 feet. Ostriches are omnivorous and feed on a variety of plant matter, insects, and small animals. They are known for their speed, being able to run at speeds of up to 40 miles per hour.
in other birds are so largely attached; in the ostrich these pectoral muscles are but slightly developed, which fact is of course in relation to its small wing. The absence of the sternal keel was the chief reason which led to the association of all the struthiones birds into one order, and the name of this order—Ratitae—emphasised the character, signifying raftlike, as opposed to Carinatae or keeled. The ostrich is now confined to Africa, Arabia, and Syria, but the discovery of its fossil remains in India indicate that it formerly had a much wider range.

The ostrich shuns the presence of man, but is often to be seen in near proximity to herds of zebras, quaggas, giraffes, antelopes, and other quadrupeds. It is gregarious, although the flocks of ostriches are not generally very large. It is polygamous, one male usually appropriating to himself, when he can, from two to seven females, which seem to make their nest in common, scooping a mere hole in the sand for this purpose. Each female is supposed to lay about ten eggs. The eggs are all placed on end in the nest, which often contains a large number, whilst around it eggs are generally to be found scattered on the sand. Concerning these, it has been supposed that they are intended for the food of the young birds before they are able to go in quest of other food; an improbable notion, not supported by evidence. It seems at least as likely that these scattered eggs are laid by females waiting whilst the nest is occupied by another, and that they are lost to the ostriches, and no more regarded. Contrary to a very generally received opinion, the ostrich does not leave her eggs to be hatched entirely by the heat of the sun; nor is it the case, as has been alleged, that the male only incubates. Both parents give their assistance in the task of watching the eggs. The male and female sit alternately on the eggs for six weeks; the cock sitting all the night, but the female helping in the daytime.

The ostrich feeds exclusively on vegetable substances, its food consisting in great part of grasses and their seeds; so that its visits are much dreaded by the cultivators of the soil in the vicinity of its haunts, a flock of ostriches soon playing terrible havoc with a field of corn. The ostrich swallows large stones, as small birds swallow grains of sand, to aid the gizzard in the trituration of the food; and in confinement it has often been known to swallow very indistinguishably whatever came in the way—pieces of iron, bricks, glass, old shoes, copper coins, &c. Its instincts do not suffice to prevent it from swallowing very unsuitable things; copper coins were fatal in one instance, and a piece of a parasol in another.

The speed of the ostrich, when it first sets out, is supposed to be not less than sixty miles an hour; but it does not seem to be capable of keeping up this speed for any length of time. It is often killed by men on horseback, who take advantage of its habit of running in a curve, instead of a straight line, so that the hunter knows how to proceed in order to meet it and get within shot. It is often killed in South Africa by men who envelop themselves in ostrich-skins, and, cleverly imitating the manners of the ostrich, approach it near enough for their purpose, without exciting its alarm, and sometimes kill one after another with their poisoned arrows. The strength of the ostrich is such that it can easily carry two men on its back. Its voice is deep and hollow, not easily distinguishable by the ear from the roar of the lion; but it more frequently makes a kind of cackling, and, when enraged and striking violently at an adversary, hisses very loudly. The flesh of the ostrich is of a coarse and inedible quality. It is game, but rank and tough when old. It is generally believed to have been prohibited as unclean to the Jews (Lev. xi. 16), although the name is translated owl in the English Bible. There are frequent references to it in the Old Testament.

The eggs of the common ostrich, which are white or yellowish white in colour, are much esteemed as an article of food by the rude natives of Africa, and are acceptable even to European travellers and colonists. Each egg weighs about three pounds, and is thus equal to about two dozen ordinary hen's eggs. The ostrich generally lays its eggs set right on a fire, and stirred about with a forked stick, inserted through a hole in the upper end. The thick and strong shell is applied to many uses, but particularly is much employed by the South African tribes for water-vessels. The render will probably recollect the interesting plate in Lee's Travels of women filling ostrich-shells with water. In taking ostrich-eggs from the nest the South African is careful not to touch any with the hand, but uses a long stick to draw them out, that the birds may not detect the smell of the hand, in which case they would forsake the nest; while, otherwise, they will return, and lay more eggs. The long plumes of the ostrich have been highly valued for ornamental purposes from very early times, and continue to be a considerable article of commerce (see below; also FEATHERS). The ostrich is often to be seen in Britain in confinement, and readily becomes quite tame and familiar, although still apt to be violent towards strangers. Great numbers were exhibited in the public spectacles by some of the Roman emperors; and the brains of many ostriches were sometimes presented in a single dish, as at the table of Heliogabalus. See the articles CASSOWARY, EMU, RHEA; also AFYORNIS, DINUINIS.

OSTRICH-FARMING.—Although there were isolated attempts in 1864, the domestication of the ostrich in South Africa, for the sake of the eggs, dates from about 1867, and so rapidly had the industry grown that in 1880 about £8,000,000 of capital was employed, and the value of feathers exported was over £800,000. The French have also made attempts in the same direction in Algeria; feathers are exported from Tripoli; there are tame birds kept in Egypt; while birds have been imported into Australia by the Melbourne Acclimatisation Society, and a shipment was made from Cape-town to Buenos Ayres in 1882. Successful experiments in ostrich-farming have also

Osmondas

Onstrog, a town of Russia, in Volhynia, 176 miles W. of Kieff. Pop. 16,522, mostly Jews.

Osrogoths. See Gothis.

Ostuni, a city of South Italy, 22 miles NW. of Brindisi by rail. Pop. 15,199.

Osuna, a town of Spain, 66 miles by rail ESE. of Seville, stands in a fertile plain on a triangular hill crowned by the castle of the Girons, dukes of Osuna, and by a collegiate church (1584), which was pillaged by Solt of 5 cwt. of ancient church plate. Pop. 15,199.

Oswald, St. King of Northumbria, was the son of the conquering Ethelfrith of Bernicia and of Aeva, sister of the brave Edwin of Deira. He fought his way to the throne by the defeat, at Heavenfield near Hexham (653), of Ceddwalla the Welsh king who had aided Penda to crush Edwin at Hatfield two years before. Under the reign of Edwin he had found shelter in Scotland, and been converted to Christianity at Hii or Iona; and now, when he was hailed king by the whole of Northumberland, he established Christianity with the help of St Aidan, who settled on Holy Island. Oswald was acknowledged by all the kings save those subject to Penda. He fell fighting against his enemy at Maserfield (Oswestry) in 642.

Oswego, a port of entry and capital of Oswego county, New York, is situated at the mouth of Oswego River (here crossed by three bridges), on Lake Ontario, at the extremity of the Oswego Canal (to Syracuse, 33 miles by rail), and 326 miles by rail NW. of New York City. It is a handsome city, with wide streets, and a United States government building, court-house, city hall, state armory, &c. It is the principal port on the lake, with a breakwater, a dozen large elevators, and 4 miles of wharves, and carries on a large trade. The river falls here 34 feet, and the abundant water-power is utilised in flour-mills, knitting-mills, &c. Oswego starch and corn-flour are as well known in Europe as in America. Pop. (1890) 21,116; (1900) 22,199.

Oswego Teu, a native; given to several species of Monandra, particularly M. purpurea, M. dilatana, and M. kalminna, natives of North America, because of the occasional use of an infusion of the dried leaves as a beverage. They belong to the natural order Labiate, somewhat resembling mints in appearance, and have an agreeable odour. The infusion is said to be useful to the lungs and intermitting fevers.

Some other species of Monandra are used in the same way, and the three species named are not uncommonly cultivated in gardens for ornament.

Oswestry, a thriving market-town and municipal borough (1397) of Shropshire, 18 miles NW. of Shrewsbury. It has an old parish church, restored in 1872 at a cost of £10,000; a fragment of the Norman castle of Walter Fitzwalter, progeny of the royal Stewarts; and a 15th-century grammar-school, rebuilt in 1810 and enlarged in 1863-78. Railway workshops were established in 1863, and sewerage and water works constructed in 1866. Oswestry derives its name from St. Guthlac (q.v.), who was slain here. In 1644 it was captured by the parliamentarians. Pop. (1861) 4817; (1881) 7847; (1891) 8490. See works by Price (1815) and Cathrall (1855).

Osy mundas, the name of a great king of Egypt, mentioned by Dioscorides and Strabo, who reigned, according to these authors, as the 27th successor of Menes, and called a Hebra by his victories, to have invaded Asia with an army of 400,000 men and 20,000 cavalry, and to have conquered the Bactrians, who had been rendered tributary to Egypt by Sesostris. In honour of this exploit he is said by Heeaeus to have erected a monument which was at once a palace.
and a tomb, and which, under the name of Oyg-
mansion, was renowned for its size and splendour
in later times. The Oysymandia was generally
believed to represent by the extant ruins of the
Ramosseum at Medinet Habu (see TREES),
though this is by no means certain. Not with-
standing the descriptions of its magnificence in ancient
writers with the dimensions of the existing relic.
Nor can the name of Oysymandia be recognised
amongst the Egyptian kings.

Otago, the most southern provincial district of
New Zealand, in the South Island. It was one of
the last portions of the country to be explored,
but since 1876 these have been abolished and the county
system has been adopted. The name is said to be
derived from the Maori Otakou, 'red earth.'
It was colonised in 1848 by the Otago Association
connected with the Free Church of Scotland. It is
bounded on the N. by Canterbury and Westland,
and on the E. and W. by the sea. It has a coast-
line of 400 miles, is 160 miles long by 193 broad,
the estimated area comprising 15,088,300 acres,
of which 9 million, chiefly in the centre and in the east,
are under cultivation. Pop. (1880) 158,219; (1891)
153,097. Gold was discovered here in 1861,
and now the goldfields comprise an area of 2\(^2\)
acres of millions of acres, from which gold to the value
of £20,000,000 had been exported up till 1895.
Dunedin (q. v.) is the capital. See NEW ZEALAND.

Otahelte. See TAHITI.

Otakina (Gr. ot-, 'the ear,' and algos, 'pain')
is neuroglia of the ear. See EAR.

Otary (Otraria), a genus of the seal family
(Balenoidea). See SEAL.

Otchankoff, a seaport of Russia, stands on
the north shore of the estuary of the Dnieper, 38 miles
ENE. of Odessa. It occupies the site of the ancient
Alector, and has beside it the ruins of the once
important Greek colony of Olbia. In 1492 the khane
of the Crimea built here a strong fortress, which
was taken by the Turks under Muhamed in 1576,
recovered in 1738, and again captured after a long
siege by Potemkin in 1788, and definitively annexed
by Russia. After it had been bombarded by the
Allied fleet in 1855 the Russians demolished the
fortifications. In 1857 a ship-channel was opened
here, which makes the estuary of the Bug and
Dnieper much more easily accessible to large ships.
Pop. 6077.

Otman, or Osman I., surnamed Al-ghazi
('the conqueror'), the founder of the Ottoman
(Turkish) power, was born in Bithynia in 1359,
and, on the overthrow of the sultanate of Ioumiun
in 1299 by the Mongols, seized upon a portion
of Bithynia. Then he forced the passage of the Olympos,
took possession of the territory of Nicea, except
the town of that name, and gradually subdued a great
part of Asia Minor; and so became the founder
of the present Turkish empire. From his name are
derived the terms Ottoman and Osmanli as synonyms
for the Turks. See TURKEY.

Otman, third calif. See CALIF.

Otto, Marcus Salvius, Roman emperor
for the first three months of 60 A.D., was descended
from an ancient Etruscan family, and was born in
32 A.D. He was a favorite companion of Nero,
who sent him to Lucania for his refusal
to divorce his beautiful wife, Poppea Sabina.
Here he remained ten years, and ruled with wisdom
and moderation. He joined Gallus in his revolt
against Nero (68), but, disappointed in his hope
of being proclaimed Gallus's successor, marched at
the head of a small band of soldiers to the forum, where
he was proclaimed emperor, and Gallus was slain.
Otto was recognised as emperor over all the Roman
possessions, with the exception of Germany, where
a large army was stationed under Vitellius, which
at once began to march on Italy under the com-
mand of the lieutenants Valens and Cecina. Otto
showed vigour in his preparations, but his forces
were completely defeated after an obstinately fought
battle near Cremona. Notwithstanding the things
were still far from desperate, Otto set his house
in order, and then stabbed himself, 16th April 69.

Otto I., or Otto THE GREAT, son of the
Emperor Henry I. of Germany, was born in 912,
and was, on the death of his father in 936, formally
crowned king of the Germans. His reign was one
of successful and generally tranquil wars, in the course
of which he brought many tur-
bulent tribes under subjection, acquired and main-
tained almost supreme power in Italy, where he
imposed laws with equal success on the kings of
Lombardy and the popes at Rome, consolidated the
disjoined power of the German emperors, and
established Christianity at many different points
in the Scandinavian and Slavonic lands, which lay
beyond the circuit of his own jurisdiction. He died
in 973.

Otis, James, American statesman, was born at
West Barnstable, Massachusetts, 5th February
1725, graduated at Harvard in 1743, practised
law, and became a leader of the Boston bar. He was
advocate-general in 1760, when the revenue officers
demanded his assistance in obtaining from the
superior court general search-warrants allowing
them to enter any man's house in quest of smuggled
goods. Otis, however, refused, resigned his posi-
tion, and appeared for the people; and his speech,
which took five hours in delivery, produced a great
impression—John Adams afterwards declared that
the child independence was then and there born.'
When the writ was again granted by the
house authorities, in 1761, Otis was elected to the
Massachusetts assembly; and he afterwards
was prominent in firm resistance to the revenue
acts. In 1769 he was savagely beaten by some
revenue officers and others, and as a result of a
sword-cut on the head he lost his reason. On 25th
May 1783 he was killed by lightning. The publica-
tion on which his fame chiefly rests is The Rights
of the Colonies Asserted and Proved (1764),
a powerful and fearless defence of their right
to control their own public expenditure. See the Life
by W. Tudor (Boston, 1822).

Otis, inflammation of the tympanic cavity
of the ear. See EAR.

Otley, a market-town in the West Riding of
Yorkshire, on the right bank of the Wharfe, and
at the north base of Otley Chevin (295 feet), 10 miles
N.W. of Leeds. Its church, restored in 1808-
89, is mainly Perpendicular, but has fragments of
Saxon and Norman work; there are an assize-
house (1857), a mechanics' institute (1869),
and a grammar-school (1692). Mangle-making
is the principal industry, with worsted and leather
manufactures. (Pop. (1851) 4422; (1891) 7383.

Otocyon. See Dog.

OTOMAEN. See Dog.

Otorhin, a purulent or muco-bilious dis-
charge from the external ear. See EAR.

Ottranto (the ancient Hydruntum), a town in
the extreme south-east of Italy, 29 miles by rail
SE. of Lecce, and on the Strait of Otranto, 45
miles from the coast of Albania on the opposite
side. During the later period of the Roman
empire, and all through the middle ages, it was
the chief port of Italy on the Adriatic, while
passengers took ship for Greece—having in this
respect supplanted the famous Brundisium of
earlier times; but its port is now in decay. In
Ottawa, one of the largest rivers of British North America, rises nearly 300 miles due north of Ottawa city, flows west to Lake Timiskaming, some 300 miles, and thence 400 miles south-east, and falls into the St. Lawrence by two mouths, which form the island of Montreal. Its drainage basin has an area variously estimated at from 60,000 to 90,000 sq. m. During its course it sometimes contracts to 40 or 50 yards; elsewhere it widens into numerous lakes of considerable size. It is fed by many important tributaries, the chief of which are the Petawawa, Bonnechère, Madawaska, and Rideau on the right, and the Conjoine, Gatineau, and Rivières du Lièvre and du Nord on the left side. These, with the Ottawa itself, form the means of transit for perhaps the largest lumber trade in the world. The passage of timber over falls and rapids has been greatly facilitated by the construction of dams and slides. See next article.

Ottawa, the capital of the Dominion of Canada, is situated upon the south bank of the Ottawa River, 120 miles from its influx into the St. Lawrence at Montreal. The river Ottawa drains a vast stretch of country as far north-west as Lake Nipissing and beyond; all the lumber products of this district, as well as all the local trade, are carried down to Ottawa, to the point at which the river forms the splendid Chaudière Falls (200 yards wide and 40 feet high). These falls, above which a suspension bridge spans the river, supply the motive-power for the numerous lumber-mills, flour-mills, factories, &c. To the east of the city the river Rideau forms a second fall, which, although inferior to the Chaudière, supplies further motive-power. The Rideau Canal, which was made in 1827, passes through the centre of the city, and affords connection with the Rideau Lakes, and so with the great lakes beyond. Owing to the proximity to the north-east, the Gatineau River joins the Ottawa and affords further lumbering facilities. A few miles to the east, the Du Lièvre River opens up a rich phosphate country, which is being much worked. The industries of Ottawa are mostly connected with lumber. In the winter thousands of men are engaged in cutting timber and drawing it to the streams, and in the spring the freshets carry down to the mills the rafts, on which the men who cut it live and labour during the passage. The cut of timber in the Ottawa Valley amounts to some years to over 700,000,000 cubic feet. Flour, iron wares, bricks, leather, and matches are manufactured. The exports of the city amount annually to over $3,000,000, the imports to about $2,000,000.

The parliamentary buildings, constructed in the Italian Gothic style after 1850, when the Prince of Wales laid the foundation-stone, are placed on a noble bluff on the bank of the Ottawa. These structures, including the handsome library building and the Victoria Tower (189 feet high), cost altogether about $8,000,000. The residence of the government-general—an old-fashioned building called Hull Hall—is situated about a mile from the city. The post-office, city hall, banks, and telegraph-offices are all of stone and handsomely built. The churches are numerous, but not splendid in architecture. Ottawa is the place of residence of the bishop of Ontario (Church of England), and of the Roman Catholic bishop of Ottawa, who has a cathedral here. The Roman Catholics have separate schools; the Protestants attend almost universally the public schools. There is a normal school and a collegiate institute, both public, and a very large college conducted by the Oblate Fathers; besides a ladies' college, a musical academy, and an art school. A well-equipped geological museum and the parliamentary library, with 140,000 volumes, add to the educational advantages of the city. There are general hospitals and a variety of homes for the poor. Besides the rivers and canals already mentioned, Ottawa stands on the Canada Pacific Railway, which runs along the north bank of the Ottawa from Montreal and crosses by a bridge into Ottawa; whilst the Grand Trunk Railway and the Canada Atlantic Railway meet the city with the Intercolonial Railway on the east, and with the Canada Pacific Transcontinental line. Ottawa is governed by a mayor and corporation. The taxes are high, and the streets, partly owing to the climate, are bad; but the city is improving. The city was erected in the last years of the 18th century by a settler named Wright, of Boston, Massachusetts, who built himself a residence near the Chaudière, and called the village which he founded Hull. Hull now contains 12,000 inhabitants, mainly in the lumber trade. The southern bank lots, on which Ottawa now stands, were sold by Wright to one Sparks, who took them reluctantly in payment.
for labor. In 1823 Colonel By was sent by the British government to survey the Rideau Canal. The construction of the canal (1827) stimulated the settlement, which was called Bytown. In 1834 its name was changed to Ottawa, and the town was created a city. In 1851 the population was 15,000; in 1871, 21,545; in 1881, including an increased area, 31,307; and in 1891, 44,154 (about one-half Roman Catholics); to these may be added about 15,000 in adjoining villages and suburbs. In 1838 Ottawa was chosen as the administrative capital of Canada. The first parliament met here in 1867.

**Ottawa.** (1) capital of La Salle county, Illinois, at the confluence of the Fox and Illinois rivers, which are here crossed by five bridges, 82 miles by rail WSW. of Chicago. It has a mineral spring rich in bromine and iodine, six glass-furnaces, and manufactures of flour, cutlery, tiles, fireproofing, organs, and pianos. Pop. 10,588.—(2) Capital of Franklin county, Kansas, on the Osage River (crossed here by two bridges), 35 miles by rail SW. of Kansas City. It contains a college, a foundry, and railway-shops, and manufactures flour, furniture, earriages, and soap. Pop. 6934.

**Otter** (*Lutra vulgaris*), an aquatic carnivore in the family Musteldie, which also includes the badgers and weasels. It is type of a widely distributed genus with about twenty reputed species, like one another in their diving and swimming powers, in their fish-di^et, in the webbing of the feet, and in the brown color of the short, close fur. In the common species, distributed through Europe and Asia, the body may attain a length of 2½ feet, and the tail half as much; the head is broad and flat, with short, rounded ears; the blunt snout bears lateral slit-like nostrils, closed during diving; the long body is covered with beautiful chestnut fur; the legs are very short, but strong; the feet are clawed as well as webbed. The otter lives in a hole by the stream side, and feeds especially on fish, but also on small mammals, birds, frogs, cray-fishes, &c. In strength and agility, keen scent and hearing, and general astuteness it deserves a high rank among mammals. Its life is solitary except at the pairing season in spring, after which the female gives birth to three or four blind young, which she guards with great care till they are able to look after themselves. Being very destructive to fishes, the otter has been much hunted, and is now rare where it once abounded. Isaac Walton gives a lively description of an otter-hunt, and tells us that the "fish-beast will walk upon land sometimes five or six, or ten miles in a night," that "he devours much fish, and kills and spoils much more," that "he can smell a fish in the water one hundred yards from him," that "his skin is worth ten shillings to make gloves," while "his stones are good against the Falling-sickness." The flesh is tasty, and, being for practical purposes that of a "fish," is allowed during fasts. The young may be tamed and used for fish-catching.

Among the other species the most remarkable is the large *L. sumbitches*, from Demerara and Surinam; while of related genera the most striking is the Sea-otter (*Enhydra lutris*), from the North Pacific. This is a powerful otter, sometimes 4 feet long and 90 lb. in weight, with massive molars, by which it is said to crush mollusces and crabs as well as fish. Its fur is valuable, and the animal is consequently becoming rare. Steller, who was shipwrecked on Behring Island in the middle of the 18th century, has beautifully pictured the life of this interesting otter, but its habits have now become much more shy and wary, and measures have had to be taken to prevent its extermination. The most common otter of North America is *L. canadensis*, much larger than the European species, and ranging throughout the continent, though rare in settled districts.

Otter-hunting is practised in the early morning, and at a season when all other hunting is drawing to a close. The huntsmen are armed with spears; and the true otter-hound, seen best in the Carlisle pack, is a bold, hardy, rough-coated dog, nearly two feet high at the shoulder. Foxhounds are sometimes used.

**Otterburn**, a small village in Redesdale, Northumberland, about 16 miles south of the Border, and 32 miles from Newcastle, on the henty uplands a little to the west of which was fought, during the moonlit night of 10th August 1388, what Froissart calls "the hardest and most obstinate battle that was ever fought." Of a Scottish army of 50,000 men which had mustered on the Border, the greater part invaded England by Carlisle, while 3000 foot and 300 lancers under the Earls of Douglas, Dunbar, and Moray remained to carry fire and sword through Northumberland and Durham. On the march back, laden with spoil, they lay three days before Newcastle, and in one of the frequent passages of arms that occurred Douglas carried away Hotspur's pennon, and declared that he would plant it on his castle of Dalketh. By God, Earl of Douglas," said Hotspur, "you shall not even bear it out of Northumber-land." The Scots marched up Redesdale, and, after failing in an attempt on Otterburn Tower, by the desire of Douglas entrenched themselves on a hill slope near, the exact site of which is somewhat uncertain, in order to give Percy an opportunity of coming to claim his pennon. The chivalrous Hotspur hastened after them with 600 horse and over 8000 foot, and came up while the Scots were at supper, whereupon a desperate hand-to-hand fight at once began. Douglas was greatly outnumbered in numbers, and, seeing his men forced back, grasped his ponderous mace in both hands.
and hewed a way before him until he was borne down mortally wounded by three spear-thrusts.

To some of his kinmen anxiously asking how he did, Hume of Godscroft tells us the dying hero made answer, 'I do well, dying as my predecessors have done before; not in a bed of languishing sickness, but in the field. These things I requite for you as my last petitions: first that ye keep my death close both from our own folk and from the enemy; then that ye suffer not my standard to be lost, or cast down; and last, that ye avenge my death, and bury me at Melrose with my father. If I could hope for these things I should die with the greatest contentment; for long since I heard a prophecy that a dead man should win a field, and I hope in God it shall be.' Towards morning the Scots gained a complete victory, losing 300 men, while the English lost 1880, and among the prisoners both Hotspur and his brother Ralph. The Scottish ballad of 'Otterburn' is almost as historical as Froissart's glowing narrative; the English 'Ballad of Chevy Chase' is a glorious effort of the imagination, which still stirs a modern reader, as did Sir Philip Sidney, more than the blank verse. See Sir Walter Scott's 'Marmion,' 'History of the Battle of Otterburn' (1837).

**Otter St Mary.** a town of Devonshire, on the river Otter, 11 miles (15 by rail) E. of Exeter. Twice the scene of a great conflagration, in 1767 and 1866, it retains its magnificent collegiate church, a reduced copy of the cathedral of Exeter (q.v.), with the only other transeptal towers in England. It contains a large moiety by William Ironescombe, it is Early English, Decorated, and Perpendicular in style, and was restored by Butterfield in 1849-50. The old King's Grammar-school was demolished in 1834. Alexander Barclay was a priest here; Coleridge (q.v.) was a native; and 'Clavering' in *Pendennis* is Ottery St Mary, the Devonshire residence of Thackeray's stepfather. Silk shoe-laces, handkerchiefs, and Honiton lace are manufactured. Pop. (1881) 973; (1891) 3855.

**Otto.** See ORTH.

**Otto, or Attar, of Roses** is the volatile oil or otto of the petals of some species of rose, obtained by aqueous distillation, and highly prized as a perfume. It is a nearly colourless or light-yellow liquid, of a sweet rose-scent.

F. liquefying a little above that temperature. It is imported from the East, where in the Balkan Peninsula, Syria, Persia, and India roses are cultivated to a considerable extent for its sake. It is probable that the oriental otto is the produce of more than one species of Rose (q.v.); it is uncertain what species is cultivated in some of the localities most celebrated for it, but *Rosa damascena* is known to be so employed in the north of India, and a kind of otto is sometimes obtained by the makers of rose-water from *Rosa centifolia* in Egypt, near Alexandria, is celebrated for its rose-gardens, which surround the town, and are in reality fields occupied by rows of low rose-bushes, extending over 100 acres. Cashmere is noted for its extensive manufacture of otto, as are also the neighbourhoods of Shiraz andDamascus. Rezanik is the commoner name for the rose-growing district in the Balaikhan, which is 40 miles long; *Rosa mocinana* affords the chief supply. The gathering is commenced on the third year, and is carried on chiefly in May and June. About 7000 lb. of petals are required to produce 28 lb. of otto, or about the gathering of 29 acres. The price ranges from £12 to £15 per lb. and the annual product in Rome is may be £80,000 in good seasons. The French perfumers buy the first quality, Austria and America the second. In the south of France about 30 million pounds of roses are gathered annually for oil distillation at about 2s. 3d. per lb. According to some calculations, 250 to 300 lb. of rose-petals are required there to produce an ounce of otto by ordinary distillation. To procure the otto, the rose-petals are usually distilled with about twice their weight of water, and the produce exposed to the cool night-air in open vessels, from which the thin film of otto is skinned with a feather in the morning. Otto is said to have been first procured by what may be called an accidental distillation of rose-petals exposed with water to the heat of the sun, and to have been found floating on the surface of the liquid, and sometimes obtained in India by such a process. It is said to be also obtained by dry distillation of rose-petals at a low temperature. During the distillation of rose-petals a small quantity of a solid volatile oil comes over, which crystallises and floats on the water in the receiver; this is sometimes called English Oil of Roses. Otto of roses is not unfrequently adulterated with geranium-oil, sandalwood-oil, oil of rhodium, &c. It is much used for making hair-oil, a drop of it being enough to impart a pleasant odour to a considerable quantity; olive-oil scented by a few drops of it is often sold under the name of otto of roses. It is also used in making lavender-water and other perfumes. The odour of otto itself is too powerful to be altogether pleasant, and frequently gives headache. Another method of obtaining the *sent* of roses is described in the section below: *Corsavy.* Otto of roses is one of two volatile or essential oils; the one solid at ordinary temperatures, and the other liquid. The liquid oil of roses (élépétine of oil of roses) is a very fine odourant substance. The otto of roses is sometimes used as a solution of one part of the solid oil in two parts of the liquid. Medicines are occasionally perfumed by otto of roses, and it is sometimes added to ungents and spirit-washes.

**Ottoman Empire.** See TURKEY.

**Ottellite.** a silicate of alumina with protodicles of iron and manganese and water. It occurs in the form of thin hexagonal plates or tablets in certain iron beds of less metamorphosed slates, which are hence termed *Ottellite-slate.*

**Ottumwa.** capital of Wapello county, Iowa, on both sides of the Des Moines River, 75 miles by rail W. by N. of Burlington, in the heart of the state's bituminous coalfields. The residence portion extends along the high bluffs. A number of railways meet here; the general passenger depot cost $125,000. Extensive dams concentrate the river's water-power; and the numerous industrial works include planing, flour, starch, and linseed-oil mills, foundries, plough, cutlery, and screen factories, bridge-works, cooperages, manufactories of furniture, bakeries, &c., and a large pork-packing establishment. There is a normal school here. Pop. (1890) 14,061; (1900) 18,197.

**Otway, Thomas.** one of the greatest masters of English tragedy, of whose life, says Dr Johnson, 'little is known, nor is there any part of that little which his biographer can take pleasure in relating; but it was darkened by the shadow of misfortune.' He was the son of the rector of Woolbeding in that county, and entered Christ Church, Oxford, as a gentle-man-commoner in 1669. He was a brilliant and impulsive youth—'charming his face was, charming was his verse,' says Dryden, but his life through all was marked by the shadow of misfortune. He made a wretched failure as an actor in *Alphsl Bein's Ford's Marriage* in 1671, declined the church, and left the university without a degree in 1672, and next year obtained a curacy in a troop of horse. A year later he was settled in London, and
had a tame and conventional tragedy, *Achabnaides*, accepted at the Duke's Theatre, which was managed first by Davis, then, and by Betterton. In the beautiful Mrs Barry made her first appearance, and with her the hapless poet quickly fell in love. In 1676 Betterton accepted Don Carlos, a great tragedy in rhyme, nervous and full of pathos, but the authorship of York demands that, like one of his greatest plays, he owed to the Abbé St-Réal. The year after Otway translated Racine's *Titaus et Berénice*, as well as Molière's *Chats de Scapin*. The intrigue between Rochester and Mrs Barry now became more than he could bear, and, through the intervention of the Earl of Peterborough, friend, and one of the king's bastards, he received a cornet's commission again, and went a-soldiering to Flanders. It proved a complete fiasco, and he soon came back to his infatuation, miserable and unpaid, a butt for Rochester in his poor and spiteful *Sentence of the Poet*. In 1679 he had produced a poor comedy, *Friendship in Fashion*; in 1680 another, *The Soldier's Fortune*, full of touches of autobiographical detail. He was ever improvident and dissipatid, and his affairs by this time had become desperate, but the death of his rival in 1680 seems to have made a great difference to him, and to shift off his burden of debt. That year yielded two tragedies, and his one important poem, *The Poet's Complaint of his Muse*, a rough, but firmly drawn satirical portrait of himself and his principal enemies, Rochester, Shadwell, and Settle. Of the principal works of *The Orphan* and *Othello*, the latter, marred by many faults in plot besides its radical indelicacy, but stamped throughout with power and sovereign pathos, wherein his central figure, Monimia, says Mr Gosse, perhaps more truly than any other sonority or heroine. The other was *The History and Fall of Caius Marius*, confessedly a kind of cento from Shakespeare's *Romeo and Juliet*, with touches from *Julius Caesar*. The year 1682 saw his greatest work, *Venice Preserved*, or *A Plot Discovered*, a noble mystery play admirably constructed, its heroine Belvidera a delightful creation of almost the highest order of dramatic genius. The only blot upon its perfection is the comic passages, which M. Taine alone among critics finds Shakespearean. Otway's mistress was now at the heart of the Island in St. Mary's Mount, and Belvidera had taken the town by storm. Six letters of his to her are extant, written apparently about 1682, which tell us the touching story of his faith and of her cruelty, how she played with his passion for seven years, and at last broke his heart. From this time he sinks out of sight, drowned in dissipation, debt, and misery. He reappears again in 1684 with *The Atheist*, a feeble comedy, and, on the death of Charles II. in February 1685, with *Windhow Castle*, a poem addressed to the new king. But his claims were neglected, and he was out the ruins of his wasted life in abject misery in a spaying-house or tavern on Tower Hill. Here he died, April 14, 1685, choked, it is said, after a long fast, with a piece of bread, which he had rushed in the eagerness of hunger to buy with a guinea given him by aussie stranger from whom he had begged a shilling.

In 1710 a badly edited tragedy, *Heroick Friendship*, was published as his, and Mr Gosse thinks that, imperfect as the execution is, the plot and ideas are characteristic of Otway. The best edition of his works is still that by Thornton (3 vols. 1819). Otway owed much to Corneille, and was long popular in France, despite the severe and unjust judgment of Voltaire. His life recalls the tragic history of Marlowe, just as his greatest play reminds a reader of *Othello*. Strong without bombast, its exquisite love-scenes between Iallier and Belvident lender without weakness, "It is simply," says Mr Gosse, "the greatest tragic drama between Shakespeare and Sheridan." One of the dead white of the Restoration, with all its bustling talent and vain show, this one solitary work of supreme genius arose unexpected and uninimitated."
battle of Ostrołęka (18th February 1807), and grew to contribute to the success of the French in Friedland. He sustained his now brilliant reputation in the second Austrian campaign of 1809, and was created Marshal of France and Duke of Reggio. In 1810 he was charged with the occupation of Holland, was engaged in the disastrous Russian campaign, and subsequently took part in the negotiations of 1813 between the French and the Russians and Austrians. He was one of the last to abandon Napoleon, but he did so for ever, and spent the period known as the 'Hundred Days' on his own estates. At the second restoration he became minister of state, commander-in-chief of the royal guard and of the national guard, and was created a peer of France, Grand Cross of St Louis, &c. In 1823 he commanded the first division of the army of Spain, and was for some time governor of Madrid. After the revolution of July 1830 Oudinot retired to his estates; but Louis-Philippe in 1842 appointed him governor of the Invalides. He died at Paris, 13th September 1847. See his Life by Nollet (Paris, 1840).—His son, CHARLES NÎCÂLAS-VICTOR OUENOT, Duke of Reggio (1791-1868), was a general in the Napoleonic wars. He first distinguished himself in Algeria, and was general of the French expedition against Rome in 1849.

Ouida, the pseudonym of the novelist LOUICE DE LAMÉ, who was born about 1840, and who spent part of her girlhood with her mother at Bury St Edmunds. About 1874 she was living in London at the Lambs, and soon after began to write. She was writing for Colburn's New Monthly and Bentley's Magazine as early as 1861; and among more than a score of novels by her may be mentioned Strathmore (1865), Idalia (1867), Under Two Flags (the best, 1868), Flick (1869), Folle Pariny (1871), Posey (1873), Arraucan (1877), Moira (1880), Princess Napaizine (1884), Santa Barbara (1891), The New Priesthood (1893), The Silver Christ (1894), Toxin (1895), The Massacre of 1807. Muscular heathenism, nature-roworship, and an encyclopedic ignorance are prevailing notes of these books, which are clever but uninteresting. There is a faint note of 'glamour' and glitter, and withal a singular sameness—nowearying of their courtesans and blasé aristocrats, and ceases to be amused with their classical and cosmopolitan malapropisms.

Outisli. See MARMOSSET.

Outlaclan. See CANDLE-FISH.

Outless, WALTER WILLIAM, portrait-painter, was born 21st September 1848, at St Helier's, Jersey, and educated at Victoria College, Jersey. He began to study art in London in 1864; four years later first exhibited at the Academy; and became an A.R.A. 1877, an R.A. in 1881. Of his portraits perhaps that of Darwin is most generally known on account of the very fine etching from it by John Hollingworth. Mr. Outless never paints a commonplace portrait, his work is always remembered, and his subjects are too great a student of character to make his art the medium of flattery. His portraits of Justice Minnis and Cardinal Newman are fine examples of his different methods.

Ounce [Lat. uncia, the twelfth part of the as or libra (pound), or indeed the twelfth part of any monetary exaction, rate, or custom. Hence inch, the twelfth part of a foot. In Troy weight the ounce is divided into 480 grains, and 12 ounces make a pound; the ounce in Avoirdupois weight contains 437½ grains Troy, and 16 of them go to the pound.

Ounce (Félix uncia), a feline carnivore like the leopard, but with lighter, longer fur, and with a skull unusually broad for one of the Felidae. It frequents the mountains of central Asia. It may also be noted that a somewhat similar title, Felidae once, belongs to the jaguar.

Oudle, a small but ancient and pleasant town of Northamptonshire, 13 miles SW. of Peterborough by rail, has an old church, partly Early English and partly Decorated style, restored in 1864. Here St Wilfrid died. Laxton Grammar-school dates from 1535, and the Church is made here. Pop. 2500.

Ourari. See CURARIL.

Ourro Preto ('Black Gold'), capital of the state of Minas Geraes in Brazil, stands among barren mountains, 3780 feet above sea-level, and 200 miles N. by W. of Rio Janeiro. It contains several handsome official buildings, but otherwise consists mainly of narrow and irregular streets. The gold-mining is now reduced to comparatively unprofitable washings. Pop. (1880) 22,000.

Ouse, a river of Yorkshire, formed by the union of the Swale and the Ure in the immediate vicinity of the village of Boroughbridge, and flowing south-eastward past York, Selby, and Goole. About 8 miles below the last town it joins the Trent, and forms the estuary of the Humble (q.v.). The length of the Ouse, from Boroughbridge to York, is 67 miles; for the last 43 of which (from York) it is navigable for large vessels. Its principal affluents are the Wharfe and the Aire from the west, and the Derwent from the north-east. The basin of the Ouse, or the Vale of York, commences about the northern boundary of the county near the river Tees, from whose basin it is separated by a low ridge of hills, and extends southward, including almost the whole of Yorkshire (q.v.).—The GREAT OUSE, rising close to Brackley, in the south of Northamptonshire, flows north-eastward through the counties of Buckingham, Bedford, Huntingdon, Cambridge, and Norfolk, till it falls into the Wash, 23 miles below Lynn. It is 160 miles in entire length, and is navigable for about 50 miles. It receives the Ivel, Cam, Lark, and Little Ouse.

Ouseley, Sir FREDERICK ARTHUR GORE, musician, was born on 12th August 1825, and at the age of nineteen became a member of the music staff of the Royal Academy of Music (1770-1814), the celebrated Orientalist and first baronet. He graduated at Christ Church, Oxford, and took orders, his first curacy being at St Paul's, Knightsbridge. In 1855 he followed Henry Bishop as professor of Music at Oxford, and, in 1859, became M.D. of St Michael's, Tenbury. He had an immense knowledge of music, extending from St Ambrose to Wagner. His mastery of the literature of music is seen in his edition of Neumann's History of Music, and his treatises on harmony published in the 'Clarendon Press' series have taken their place as standard works. He was an accomplished linguist, and collected a magnificent library. His oratorios St Polycarp and Hagar are too solid and severe to be popular, but will always command respect. Haver- gdh's Memorials of P. A. G. Ouseley, published after his death in 1886, is a collection of contemporary opinions pronouncing him a perfect gentleman, a skilled musician, and a churchman who devoted the whole of his fortune to building and endowing St Michael's College, Tenbury, for the training of choirmasters. See Life by Joyce (1896).

Outcrop, in Geology, the name given to the edges of strata which are thrust out at the surface. The same term is applied to the line along which a mineral vein or lode comes to the surface—although other terms, such as 'outgoing,' 'back,' are also employed by miners.

Outlawry, in English law, means putting one out of the protection of the law, for contempt
OVAROTOMY

in wilfully avoiding execution of legal process. Formerly, in the common law courts, if the defendant would not enter an appearance certain proceedings were taken to outlaw him, so as to allow the action to go on without his appearance. These proceedings, however, were abolished in 1879, and, in the majority of cases, it is immaterial as regards the action whether the defendant appear or not. Provided he was properly served with the original writ of summons. After judgment a defendant against whom a copias was granted might be outlawed if the sheriff failed to find him. These forms of process are now obsolete. In criminal proceedings it is still a peril an outlaw now cannot be found and arrested. But a criminal who flees the country may now, as a general rule, be made amenable to justice by applying to a foreign government for his Extradition (q.v.). Outlawry therefore is practically obsolete. See Stephen's Criminal Procedure.

The effect of outlawry was that a man forfeited his rights, and was precluded from suing or defending in any English court; but the outlawry might be reversed by means of a plea of or proceedings in Error (q.v.).

Outram, Sir James, the 'Bayard of India,' was born at Burton Hall, Derbyshire, the residence of his father, Benjamin Outram (1794-1895), a well-known engineer. His mother in 1810 removed with her five children to Aberdeen, where and at Udny James was educated. After one session at Marischal College, in 1819 he received admission to Westminister, and in 1823 was appointed to the rank of adjutant in the Bombay native infantry. Between 1825 and 1835 (in which latter year he married his cousin, Margaret Anderson) he successfully organised a corps of the wild Balis; from 1835 to 1838 he was political agent to the Mahi Kantha district in Bengal, where he rendered most able service as aide-de-camp into Afghanistan (q.v.); and his eight days' ride of 355 miles, disguised as an Afghan merchant, from Klat, through the perils of Bolar Pass, to the sea, will long be famous in eastern annals. Appointed in 1840 political agent of Sind, he distinguished himself by his heroic defence of the British Residency at Hyderabad against 8000 Beluchis (15th February 1843), as also by his manly opposition to what he deemed Sir Charles Napier's aggressive policy towards the Amur. He was afterwards political agent of Sattara and Baroda, and in 1854, on the eve of the annexation of Oudh, was selected by Lord Dalhousie for the highest political office in India—the Residency of Lucknow. In 1857, after a short brief furlough to Europe, he commanded the Persian expedition—a short, brilliant campaign, whose objects triumphantly attained, he returned to India a G.C.B. (he had been knighted sixteen months before). When he landed in July the Mutiny was raging; and Lord Canning tendered him the command of the forces advancing to the relief of Lucknow. He bravely waited in front of his old lieutenant, Havelock (q.v.), who already had fought eight victorious battles with the rebels; and accompanied him only as chief-commissioner of Oudh, whilst tendering his military services as a volunteer. Lucknow (q.v.) in his service he was 1858 promoted to the rank of lieutenant-general, thanked by parliament, and created a baronet. He took his seat as a member of the Supreme Council at Calcutta, but in 1860 had to return to England, already stricken by the hand of death. He spent the winter of 1861-62 in Egypt, and, after a short stay in the south of France, expired at Paris, 13th March 1863. He was buried in Westminster Abbey; and statues of him have been reared in London and Calcutta. See his Life by Major-general Sir F. J. Goldsmid (2 vols. 1880).

Outrigger. See Boat.

ouvirandra, or Ouvirandro. See Lat-tice Leaf, Aquatic Plants.

Ouzel, or Ouse (Old Fr. oisse, "bird"); an old name of the blackbird (as in Midsummer Night's Dream). But it was applied to other birds. Thus, one British thrush (Turdus torquatus) is called the King Ouzel, and the Dipper (q.v.) is very generally known as the Water Ouzel.

Ovamus, or Ovami, also called Otjiherero, an industrious and peaceful Bantu people of the west coast of Africa, inhabiting the country south of the Conone. Ovamoland is accordingly in the German protectorate, and extends from Dannarland northward to the Portuguese frontier. Some 50 miles from the coast the country rises into a lofty tableland, which is moderately fertile, and then declines to the south and east into the deserts of the Kavire and the Lake Ngami. Many strong indications of copper ore are found in various places. Ivory is still traded in.

Ovariotomy. in Surgery, the excision of the ovaries. The ovaries in the female are analogous to the testes in the male, and are two oblong flattened bodies (about an inch and a half in length, the follicles, or ovum-cases, the medullary portion, nearly half an inch thick in the human subject), situated on either side of the uterus, to which they are connected by ligaments and by the Fallopian tube. The ovary is composed of two well-defined portions, a superficial or "cortical" portion, and a deep or "medullary" portion. The whole surface of the ovary is covered with a tough fibrous coating, which is, however, closely blended with the cortical portion, and cannot be stripped off. It is termed the tunica albuginea. The medullary portion is highly vascular, and of a reddish colour. The cortical portion in the adult ovary contains an enormous number of vessels, varying greatly in size. These are the Graafian follicles, and contain the ova or germs—the female element of reproduction. Their number is estimated at 30,000. From ten to twenty large and more or less mature graafian follicles, and from three to ten small ones, to which they gradually approach as they become developed. The structure of these ovisacs and their contained ova is somewhat complex, and cannot be described here. More or less coincident with menstruation is the process of ovulation, by which is meant the rupture of the wall of Graafian follicle, and the escape of the contained ovum. On its escape from the ovary the ovum enters the end of the Fallopian tube, by which it is conveyed into the uterus.

The ovary is the subject of several diseased conditions. (1) It is the seat of acute and chronic inflammation. This may arise from injuries during labour, operations in the pelvis, but very frequently is the result of gonorrhoeal infection, spreading from the vagina. Such inflammations cause great organic changes in the structure, often leading to sterility, and they are usually associated with severe pain, frequently so intense as to unfit the subject for all active duty. (2) The ovary is the seat of new growths, which may be of several varieties. Some represent enlargements of one or more Graafian follicles; others are cysts sometimes weighing 100 lb. or more. They contain fluid which is usually of a viscous,ropy nature, and brownish colour, but sometimes presents other characters. These are known as ovarian cysts. Other tumours are of a more or less solid nature, and contain portions of hair, teeth, bone, &c., and
are known as dermoid tumours. Moreover, the ovaries may become the seat of cancerous disease with or without the occurrence of such tumours.

Ovary. In Botany, the part of the Pistil (q.v.) containing the Ovule (q.v.). See FLOWER, FRUIT, SEED.

Ovulation. See Triumph.

Ovary. The removal of the offending organ is one of the triumphs of modern surgery. Formerly relief in cystoanoma was only obtained temporarily by tapping—i.e. withdrawing some of the fluid by means of a treasur and cannula. But the tumour almost always filled again, and, though tapping might be repeated time after time, the patient ultimately succumbed. Now the abdominal wall is laid open, the tumour emptied as much as possible of its contents, the collapsed sac drawn through the incision, its neck secured by ligature or otherwise, the mass cut away, the stump returned to the abdomen, and the wound carefully closed by stitches.

Towards the middle of the 19th century the operation was performed by a few surgeons, under the protest of the great majority of the medical profession; now it takes its place as a routine operation, demanded in any suitable case, and performed with results as regards the saving of life and restoration to health, together with an immunity from risk, which can be claimed by no other major operation. The operation for extirpation of ovarian cystoma was first performed by Ephraim McDowell of Kentucky in 1809, but was established in England as a regular operation by Charles Clay of Manchester, who operated on his first case in 1842. Clay operated on nearly 400 cases with 60 per cent of recoveries. Since then the operation has been performed many thousands of times, and the mortality has been reduced to a figure which renders the operation, while always one of the gravest, yet, in competent hands, one of the safest in surgery. To this result the labours in Britain of Spencer Wells, Thomas Keith, and Lawson Tait have mainly contributed.

The conditions which are considered as demanding this operation are: (1) Chronic inflammation in the ovaries or tubes, resulting in the formation of pus, &c. in the latter, or giving rise to intolerable pain and discomfort, and rendering life utterly miserable; (2) cases of fibroid tumour of the uterine, in which life is threatened by the great loss of blood which these tumours often cause. Removal of the ovaries in these cases when possible is usually followed by cessation of growth and shrinking of the tumour, and entire subduing of symptoms of serious nature.

Consult Diseases and Treatment of Abdominal Tumours, by Sir Spencer Wells (1885), and Diseases of Women, by Lawson Tait (1885).

Oven. The old type of baker's oven, still very largely used, is a low arched chamber either of brick with a tile or stone sole, or built entirely of stone. A common size of sole is 11 feet 6 inches by 9 feet 6 inches (some are smaller), with sides 18 inches high, from which the crown or arch springs. The door is in front, and the dough is put in with a long wooden spade called a 'peel.' In one class of these ovens the fireplace or furnace is placed in the front corner, with an opening admitting the products of combustion directly into the oven, while there is an exit flue on the other side. This furnace is fired from the bakehouse; coke or coal is used for fuel, and any smoke is mostly cleared away during the heating up of the oven. Sometimes the plan of having a fixed fire within the oven itself is adopted, and another way is to have a movable iron furnace, called a 'chaffer,' which can be shifted from place to place, so as to evenly heat the oven. For this inside firing wood is the best fuel. In Scotland a peculiar sort of stone is used for the construction of oven soles. It is a kind of serpentine, is of a refractory nature, and is called "lakestone" or "leekstone." This rock, termed by geologists pierite, is quarried at Blackburn, near Bathgate, and two or three other places in Scot-
this method of heating. A recent form is known
as the Weighorst steami-heated oven. It has a draw-
plate, and is generally arranged so as to be service-
able for cooking meat, roasting potatoes, coffee, &c., as well as baking bread. In those for the
field portability is a main essential. For biscuit
ovens, see BISCUTS. Coke-ovens are described
under COKE.

Oven-bird, a genus (Furnarius) and sub-
family (Furnariinae) of Passerine birds, family
Dendrocolaptidae. The name is given because
some of the species build nests resembling an oven
or bee-hive. The genus, which consists of nine
species, is exclusively South American, ranging
from Guiana and Ecuador to the La Plata. The
habits of these birds have been described chiefly
by Mr Edward Bartlett, and by Darwin in his
Voyage of the Beagle. The name oven-bird is also
applied, for a similar reason, to the willow-wren
(Phylloscopus trochilus).

Overbeck, Johann Friedrich, painter, was
born at Lübeck, 4th July 1728, and commenced his
artistic studies in 1756 under the influence of
that of the classical school of David; but, having
adopted notions on art essentially different from
those inculcated in the academy, he was expelled
along with some like-minded friends, and in 1789
set out for Rome. His principle was to abjure the
classical Renaissance and its sensuousness, and to
‘abide by the Bible.’ In Rome he was joined by
Cornelius, Schadow, Schorr, and Vei; and these
five laid the foundation of a school that influenced
the taste for art in Europe, though they were scouted
at as ‘Pre-Raphaelites,’ ‘Nazarenes,’ ‘Chiclite
Romantic painters,’ and had long to struggle with
poverty. A picture of the Madonna, which Over-
beck painted in 1811, brought him into marked
notice. He was next employed by the Prussian
consul, Bartholby, to execute for his house at Rome
four frescoes illustrating the life and history of
Joseph and the ‘Seven Lean Years’ being the subjects assigned to Overbeck. After
completing these he painted in fresco, in the villa of
the Marchese Massimo, five large compositions from
Tasso’s Jerusalem Delivered. In 1813 he abandoned his Roman career and entered the Roman
Catholic religion. Overbeck’s chief work is a
fresco at Assisi, ‘The Vision of St Francis,’ His oil-pictures are inferior to his frescoes, being dry
and weak in colour. Among his famous pictures are
‘Christ’s Entry into Jerusalem,’ at Lübeck; ‘Christ’s Agony in the Garden,’ at Hanburg; ‘Le Sposalizio,’ at Berlin; ‘The Triumph of Religion in the Arts,’ at Frankfort; the ‘Incredulity of St Thomas,’ in London. He executed a great
many drawings and cartoons remarkable for
devotional feeling, most of which, like his fresco-
coes and paintings, have been engraved. One of
his last undertakings was a series of designs from
the Evangelists, delicately engraved in the
line manner. Amongst the characteristics of
the school are devout feeling, hardness of outline,
simple composition, and above all, the sublimity
and sensuous beauty both in colour and form. Over-
beck died at Rome on 12th November 1809. See
Life by J. B. Atkinson (1882), in ‘Great Artists’
series.

Overbury, Sir Thomas, was born in 1581 at
Compton-Scorpon, in Hinlington parish, Warwick-
shire, his father being squire of Bourton-on-the-
Hill in Gloucestershire. After three years at
Queen’s College, Oxford (1598–98), he studied
while at the Middle Temple, and travelled then
on the Continent, returning to an accomplished
gentleman. In 1601 at Edinburgh he met Robert
Carr, then page to the Earl of Dunbar, and the
minion afterwards of James I., who knighted him
in 1607, and in 1611 made him Viscount Rochester.
The two became inseparable friends, and Overbury
himself was, through Carr’s influence, knighted in
1608, the year before his second visit to France
and the Netherlands. Meanwhile, in 1606, the
lovely but profligate Frances Howard (1592–1632)
married the third Earl of Essex (q.v.), and during his
absence he became engaged in love with a lady with
more than one lover—Carr the most favoured.
Overbury had played pander to their guilty inter-
course; but Carr now telling him that he purposed
to get Lady Essex divorced from her husband, and
then to marry her, he strongly deprecated the idea,
delivered to him the name of a mistress but not for
a wife. Carr informed Lady Essex what Overbury
had said of her; she became furious for revenge, and
offered Sir Davy Wood (between whom and Sir
Thomas there was a standing feud) £1000 to
assassinate him—an offer prudently declined,
except under promise of assurance and a meeting
at Brindisi. From this time onwards, Overbury,
who had been married with great pangs, and the
whole affair was soon to appear forgotten.
But in the autumn of 1615, after Villiers had
largely supplanted Somerset, an enquiry was in-
sstituted, and four of the humbler instruments were
promptly arrested—among them Miss Mayne, who
in the summer of 1616, in Overbury’s service
at the Hague, first met the French poet who
later married her, and who has been described
by himself as the Beau Brummell of society. In
September 1616 he wrote to his wife to persuade
her to come over to London. In October he
was in London, and in November in France, and
in December the news of his wife’s return
brought him back to England. Meanwhile, in
1613, Overbury, on a most trivial and
illegal pretext—his contemptuous refusal to go
on an embassy—was thrown into the Tower, where, on
15th September he was poisoned. Three months
later Carr (just created Earl of Somerset) and his
paramour were married with great pangs, and the
whole affair was soon to appear forgotten.
In 1622 they were even released from the Tower;
and Somerset survived till 1628.

Overbury’s works, all published posthumously, include
The Wife (1614), a didactic poem; Characters (1614),
whose conceits are not lacking in epigrammatic point;
and Oramus suo from King James’s Table (1715).
When they were collected in 1856 his name was given
the Life prefixed. See also Andrew Ames, The Great
Oper of Poisoning (1846); Gardiner’s History of England;
Spedding’s Studies in English History (1890); and
other works cited under LITERATURE, Bacon, and
Coke.

Over Darwen. See Darwen.

Overland Route to India, Australia, and the
East is now understood to be that from England
across France, through Mont Cenis by tunnel, to
Brindisi in Italy, thence through the Levant, the
Suez Canal, Red Sea, and Indian Ocean. This makes
the journey only about half as long as the
voyage round by the Cape of Good Hope, a little
over 6000 miles instead of more than 12,000.
The saving in time is even more considerable.
The time from London to Bombay is within three
weeks, instead of three months by the Cape. In 1858
a monthly service was started to carry the mails
across Egypt; but to Lieutenant Waghorn (1800–
50) belongs the credit of first showing how the
voyage from India could be still further shortened.
On 31st October 1845 he arrived in London with
the first mails to pass the Bosphorus since the
opening of the Suez Canal (1869). The railway from
Suez to Alexandria by Cairo was opened in 1858;
but the great event that rendered the Overland
Route available for passengers generally was the
opening of the Suez Canal in 1869. See also
EUROPEAN.

Overlap, in Geology. When the upper beds of
a conformable series of strata extend beyond the
Ovid

Ovid, a poet who lived from 43 B.C. to 17 A.D., is known for his elegies and love poems. His works have been influential throughout history, and he is one of the most famous poets in Latin literature. Ovid's poetry often explores themes of love, desire, and the human condition, and he is known for his lyrical style and vivid imagery. His most famous work is the Metamorphoses, a collection of myths and legends that he translated and adapted. Ovid's influence can be seen in the works of many later poets, including Shakespeare and Milton.
in 17 A.D. This period constitutes the third of his poetical activity—in which his genius, bereft of its gaiety, responds to his invocation only in the minor notes of melancholy. Already on his last journey from Rome he began the elegies which he published in five books, by name the Triatia. Similar in time and the form of the first book of the Epistula ex Ponto, differing only in this from the Triatia that they are addressed to a particular friend in Rome—a step he did not venture on in the composition of the latter. His, written in imitation of Callimachus, in which he invokes destruction on every unknown, and his Antigeta, a poem, extant only in fragments, on the fish of the Euxine, complete the list of his remains.

In mastery of metrical form and in creative fecundity Ovid outsands all the poets of the Augustan age of which his youth up was favourably circumstances that he passed quickly through the successive stages of his development till he reached the highest perfection of which he was capable. The struggle between the new poetry and the old had issued in the subjection of the latter, under the name of inheritance prepared for him by others. This he carried to its culmination, in finish as in form. He stands at the limit of the Augustan without by a hair's breadth encroaching on the Silver age. The poetical circle in which he lived, the benevolent interest he was in favour of, and the court in which he basked, all contributed to mould his genius and stamp its products with the hall-mark of 'society.' In that world he has always been a favourite, contriving as he did to combine learning with lightness of touch, force with finish, variety with order. He knew the vie intime of the contemporaneous world, in its real as in its conventional forms, and he could sweep the collective chords of human passion, from love to hate, with the assured boldness of a master. He is the most numerous Latin poets, and in this characteristic may be found the cause of his chief defects—his self-repetition, his too frequent echoings of former felicities, the monotony of his cadences, particularly in the elegiac distich. In this metre, where the thought rarely overflows the twelve couplets, he developed his peculiar nervousness in which Quintilian traces his forensic education.

There are old translations of the Metamorphoses by Golden (1655), and Garth (q.v.), and others; and an admirable one by King (1871). Complete editions of the text are those of Bohn (1841-45); G. Friederich, Heroïdes, by A. Palmer (1874), Ibs, by Robinson Ellis (1882), and Triatia, by S. G. Owen (1890). See the fragments of Bernhardy, Tenflied, and Ribbeck; also Zingerle's Ovid und sein Verhältniss zu den Ovidianer (3 vols. 1869-71), and Rev. A. Church's study in 'Ancient Classics for English Readers' (1876).

Oviedo, the capital of the Spanish province of Asturias (q.v.), 20 miles by rail SSW, of Gijon on the Bay of Biscay and S7 N. by W. of Leon, Stand of Asturias, and lies on the rivers Nora, and sheltered to the north by a hill 470 feet high, it has four main streets, branching off from a central square, and possesses a cathedral, a university (1664), a theatre, a botanical garden, a line aqueduct, &c. The creceiform cathedral, dating from 781, and mainly rebuilt between 1588 and 1598, is a noble specimen of richly ornamented Gothic, with a tower 284 feet high, the remains of fourteen early kings and queens of Asturias, many much-prized relics, and a fine old library. In or near the city there are several Romanesque churches. Linens, woollenens, hats, and firearms are manufactured; whilst in the neighbourhood are many ironworks, and Prutia (12 miles W.) a great government foundry, producing cannon, rifles, bayonets, &c. Pop. (1887) 42,716. Oviedo, the ancient Asturum Lucum or Octavium, was known during the middle ages as Civitas Episcoporum, because many of the Spanish prelates, dispossessed of their sees by the Moors, took refuge here. It was twice plundered by the French of its ecclesiastical and other treasures, in 1809 and 1810.

Oviedo y Valdes, Gonzalo Fernandez de, born at Madrid in 1478, was sent by Ferdinand to St Domingo and to the West Indies, in 1514, as inspector-general of the gold-mines, and subsequently was appointed historiographer of the Indies. After his return to Spain he published a history thereof (1526). Of a second edition (21 vols. 1535) an English translation was made by Eden in 1550. Oviedo's Selva Acula, which appeared at Madrid in 4 vols. 1831—55. Oviedo died at Valladolid in 1557. He likewise wrote Las Naciones, a valuable gossiping account of the principal personages of Spain in his time.

Oviparous is an objectionable term applied to the great majority of female animals, whose eggs are first laid and then hatched. Ovo-viviparous is a corresponding term denoting one in which the eggs are hatched within the body of the mother, and where there is no nutritive connection between parent and offspring. Some reptiles, amphibians, fishes, &c. do not lay their eggs Illustrate this mode of parturition. In regard to the terms oviparous and ovoviviparous it would be noted (1) that all animals are in some sense viviparous, for whatever is born is normally alive; (2) that 'viviparous' animals par excellence—viz. the placental mammals—differ from 'ovoviviparous' animals, such as the brown lizard (Zootoca vivipara), the bintuworm, the black salamanderплавляющаяся, one of the blennies (Zoarcus vivipara), and many invertebrates which bring forth already hatched young; not so much in the manner of birth as in the relation between mother and offspring before birth; (3) that oviparous and viviparous parturition often occur in the same class—we witness the ovoviviparous Monotremes among mammals; (4) that oviparous and ovoviviparous parturition often occur in nearly related forms among reptiles, fishes, amphibians, and invertebrata—that they even occur in the same animal, as in the new born (Tropidonotus natrix), which usually lays eggs, but may in artificial conditions bear already hatched young; or some amphibia of the parthenogenetic generation are usually born as young insects, while the fertilised eggs are laid as such. Distinctions are the most part differences of degree.

Ovoca. See AYOC.

Ovule, a little egg; in Botany the rudimentary seed. It needs to be fertilised by the pollen tube before it can develop and grow into the seed. The ovule has a complicated structure which can only be properly understood by comparing it with the corresponding parts of the lower plants known as the Vascular Ferns. The ovule itself (q.v.), when a spore is sown a small green plant, the prothallium, grows from it; this bears male and female organs called antheridia and archegonia. A male sperm from an antheridium fertilises the egg-cell of an archegonium, and a plant which we call the fern grows from it. In other plants called heterosporous ferns, because the differentiation into sexes has been carried further back in the life-history of the plant, and the spores are of two kinds, male and female, the female prothallium grows inside the spore-case, hatching it, but not leaving it. In Conifers the prothallium is still more reduced, is surrounded by a mass of tissue called the nucellus, and also by an integument. In ordinary flowering plants the history of the ovule is as follows: On a special leaf called a carpel a mass of tissue grows called the nucellus; this
becomes entered in by two integuments which grow from its surface, but leave a small opening at the top called the micropyle. A cell near the top of the mucelle represents the mother-cell of the female spore of the vascular cryptogams. It divides into two and then into four; one of these becomes the female spore; it is called the embryo-sac because the embryos develop within it. The male spores of the vascular cryptogams are represented by the pollen grains contained in special leaves called staminoids; a pollen grain being placed on a part of the ovary sends out a tube which enters the micropyle.

The nucleus of the embryo-sac now divides into two and again nucleus travels to each end of the sac; it divides into two, then into four; the daughter-nucleus. One of these from each end travels back to the centre of the sac; they fuse and form the secondary nucleus of the sac.

The three remaining nuclei at the end near the micropyle are supposed to represent three archegonia; the three at the other end are supposed to represent the rest of the prothallus. Only one of the three archegonia—the inner one, called the oospor—will develop into the embryo if fertilised; the other two merely aid in that process. Fertilisation is effected by the pollen tube entering by the micropyle and touching one of the outer archegonia, which then breaks up and becomes attached to the oosphere; this is now called oosphere, and grows into the embryo, while the secondary nucleus of the embryo-sac by repeated division gives rise to a tissue which fills up the embryo-sac, called endosperm, rich in food materials upon which the embryo feeds. The embryo-sac at the same time grows, displacing the tissue of the mucelle. This is a generalised description. There are variations in the different orders of flowering plants, but in general the same plan is followed.

Owego, capital of Tioga county, New York, on the Susquehanna River (here bridged), at the mouth of Owego Creek, 228 miles by rail NW. of New York City. It manufactures pianos, flour, soap, leather, &c. Pop. (1900) 5039.

Owen, John, epigrammatist, was born at Aynon, in Cambridgeshire, in 1560, and had his education at Winchester and New College, Oxford, where he became fellow in 1584. He was afterwards a schoolmaster at Warwick, died in 1629, and was buried in St Paul's Cathedral. He had a great reputation in his day as a writer of Latin verse, and as the 'British Martil'! his fame as an epigrammatist was widely spread also on the Continent. His robust Protestantism sharpened into stinging wit placed his book on the Roman Index in 1654. Three books of the *Epigrammata* appeared in 1666; additions were made in later editions. The best edition is that by Renouard (Paris, 2 vols. 1795). An English translation was published as early as 1610. See *EPIGRAM*.

Owen, John, a strict Puritan divine, was born at the vicarage of Sturbridge, in Oxfordshire, in 1610. At twelve he was admitted at Queen's College, Oxford, where he worked with amazing diligence, for years taking no more than four hours' sleep a night. In 1632 he took his B.A. degree, and M.A. in 1635, and two years after he was driven from Oxford by dislike to Laud's new statutes. He teaches himself or four years of his life were spent in a state of anxious and melancholy introspection, as chaplain first to Sir Robert Dormer of Ascot, next to Lord Lovelace of Hurley; but the outbreak of the war left him without a patron, and about the same time his zealous Puritanism cost him the loss of his wealthy Welsh uncle meant to have bequeathed him. He now removed to London, where a casual sermon, preached by a stranger in Calamy's church, brought to his heart that peace he had long laboured after in vain. In 1642 he published The Display of Prophetic Truth, for which the committee for Purging the Church of Scrapling Ministers rewarded him with the living of Fordham in Essex. Here he married a lady named Rooke, who bore him eleven children. In 1646 he removed to Coggeshall, and here made public his growing dislike for the Presbyterianism and preference for a moderate form of Independent church government. The Presbyterian ministers fell upon him at once for his apostacy, but all their sermon, dogmatism, and intolerance failed to perturb his sober temper. At Coggeshall he wrote his *Salus Electorum*, *Commentary upon the 1662 Act*, his chief study, and of which he himself said that 'he did not believe he should live to see a solid answer given to it.' On April 29, 1646, he preached before parliament, and to his discourse, when printed under the title of *A Vision of Free Mercy*, he added an Appendix in which he pleads for liberty of conscience in matters of religion. He was again chosen to preach before the House of Commons the day after the execution of King Charles I. (January 31, 1649), but discreetly avoided a vindication of the act by making no reference to it whatever. About this time his time and acquaintance, and thought so highly both of his personal and his character that he carried him to Ireland as his chaplain. Here he remained about half a year, regulating the affairs of Trinity College. Next year (1650) he went with Cromwell to Scotland, and resided in Edinburgh for several months. In 1651 the House of Commons appointed him dean of Christ Church, Oxford, and in 1659 he was admitted vice-chancellor of the university. The manner in which he discharged his duties reflects the highest credit on his moderation and impartiality. In the vacant livings in his patronage were bestowed on Presbyterians; and Independents were allowed to celebrate divine worship in their own way, nor could the vice-chancellor ever be induced to offer them the slightest molestation. While at Oxford the 'Athens of Independency,' as Wood styles him, wrote his *Divinae Justitiae*, his *Doctrine of the Saints' Perseverance*, his *Vindiciae Evangelicae*—against Hibble and the Socinians—and *his Mortification of Sin in Believers*. He was one of the well-known Tiers appointed to purge the church of scandalous ministers. He explained this capacity for himself by his friendly offices on behalf of those of him and of merit like Dr Edward Pocock, Laud's professor of Arabie. Owen opposed the giving the crown to the Protector, and it appears that a coldness arose between the two. In 1657 he was succeeded as vice-chancellor of the university by Dr Conant, and the year after Cromwell's death he was ejected from his deanship. He retired to Stadham, in Oxfordshire, where he had purchased an estate, and here he formed a congregation, to which he ministered until his removal to London shortly before the Restoration. The last years of his life this period of retirement are Communion with God; *On the Divine Original, Authority, Self-evidencing Light and Power of the Scriptures; Theologonn, or De Natura, Orta, Progressum, et Studio Vera Theologiae*; and an unctuous and unreflective diatribe against the Papists is *Owen's Arminian Oration at Clarendon's request, Animadversions to Fiat Lux*, a treatise written by a Franciscan friar in the interests of Roman Catholicism. It was followed by works on *Indwelling Sin*, on the 130th Psalm, and on the Epistle to the Hebrews, the last two of which are small and elegantly written, and usually reckoned Owen's greatest work. In 1669 he published *Truth and Innocence Vindicated*, a reply to Samuel (afterwards Bishop) Parker's *Dialogue on Ecclesiastical Policy*, and in 1673 became
As a student Owen had also visited Paris and seen Cuvier, of whose school he became a prominent disciple, yet in his theoretical conclusions he rather supported Geoffroy St-Hilaire, against whose principle of the unity of organic structure he had heard Cuvier speak at the Royal Academy. Marvellous industry and width of knowledge, anatomical insight and enthusiasm for palaeontology, were as characteristic of Owen as of Cuvier, and their names will be linked while zoology lasts. Owen’s anatomical and palaeontological publications broke the 100 mark a hundred, and concern almost every class of animals from sponge to man; he helped to elucidate the structure of many rare and interesting types, such as the Venus-flower-basket (Eupodictyum), the Brachiopod Lingula, the King-crab (Limulus), the Pearly Nautilus and the Argonaut, the Mud-fish Protopterus, many extinct reptiles and birds, the recently lost Moa and the persistent Apteryx, the Aye-Aye and the Gorilla; he greatly advanced morphological enquiry by his clear distinction between anatomy and morphology, as well as by his concrete and comprehensive treatment of the subject of composition of the skull, and on other problems of vertebrate morphology; while his essay on Parthenogenesis was a pioneer work of much historical importance in connection with theories of sex and parthenogenesis (1836). As a Pre-Darwinian, many of Owen’s conclusions were opposed by the exceptionally ‘orthodox’ Owen maintained a cautious, though by no means hostile, attitude to the more detailed evolutionist theories; his convictions, in short, were those of a Platonic anatomist. He died 18th December 1892. See the Life by his grandson (1894).

Owen, ROBERT, social reformer, was born a saddler and ironmonger’s son, at Newtown, in Montgomeryshire, 14th May 1771. He had a poor education, and was put at ten into a draper’s shop at Stamford, but a few years later shifted to Manchester, and by nineteen had risen to be the enterprising manager of a cotton-mill with five hundred hands. In 1799 he married the daughter of David Dale (q.v.), the philanthropic owner of the celebrated cotton-mills at New Lanark, on the Clyde, and, having induced his firm to purchase the concern, settled down as owner, manager and partner. Here he laboured with benevolence to teach his workpeople the advantages of thrift, cleanliness, and good order, and organised with a wisdom far better than his time a system of infant education. In 1813 the business was reorganised, so as to give Owen a free hand in the management of his community. Some of the results of his research and teaching are embodied in several well-known volumes on comparative anatomy and physiology. Meanwhile he had helped to give new life to the Zoological Society of London, of which he was for a time the unpaid prosector, while he had also worked willingly in various public interests—e.g. as a commissioner of health (1843–46), and for the Great Exhibition of 1851. In 1856 he became superintendent of the natural history department of the British Museum, where he continued his investigations, and over such practical matters as the fit housing of this magnificent collection. He also continued to teach periodically at the Royal Institution and elsewhere, until his resignation of official duties in 1861, after twenty years of unfruitful effort. He died 5th November 1868. His works at New Lanark quickly became famous, and attracted visitors from all parts of the world, while his advice on social questions was sought, if not always followed, by statesmen. Owen’s thoughts on the pressing social questions of his day lifted him from him to socialism rather than co-operation as a solution, but he lost much of his influence on the wider community by utterances on religion that were at least honest, if not discreet. His sociological theories were eventually accepted by the working-class mental communities at Orkhill near Bothwell, and later at New Harmony in Indiana, at Ralahine in County Clare, and at Tytherly in Hampshire, but all were completely unsuccessful. In 1828 his connection with New Lanark finally ceased; and his life, for his part, had been occupied in the American experiment, the remainder of his days were spent in restless seculiarist and socialistic
propagandism. In his old age his mind fell into the comfortless vagaries of spiritualism. He died at his native town, 17th November 1838. — His son, Robert, born in 1807, entered Congress as a democrat in 1843. Later he helped to remodel the constitution of Indiana; acted first as charged d'affaires, next as minister at Naples (1833–58); debated divorce with Horace Greeley; supported the cause of emancipation by vigorous and able pamphlets; and made himself generally conspicuous in the campaign of spiritualism in the United States. He died on Lake George, New York, 17th June 1877. Of his books only be mentioned the spiritualistic Footprints on the Boundary of another World (1859), and Debatable Land between this World and the Next (1872); and Threading my Hay, an autobiography (1874). Two other sons, David Dale Owen (1807–60) and Richard Owen (born 1810), achieved contemporary eminence as geologists.

See Socialism; J. G. Holyoake, History of Co-operation in England (1875); Owen's Autobiography (1857), and his early life described by his son (1874); also the Lives by A. J. Booth (1869), W. L. Sargent (1890), and Lloyd Jones (ed. by W. C. Jones, 1890).

Owensboro, capital of Daviess county, Kentucky, on the Ohio, 160 miles below Louisville (112 by rail); a steam-ferry ples to Indian. The chief trade is in tobacco and whisky, there being over a score of tobacco-factories and nearly as many distilleries here and in the vicinity. The city has also foundries, and flour and planing mills, &c. Pop. (1890) 6231; (1900) 15,189.

Owens College, Manchester, which has developed into the Victoria University, owes its origin to John Owens, a Manchester cotton-spinner, who, dying in 1846, left his fortune (£20,654) for the foundation of a college on an absolutely unsectarian basis, free from all tests of creed or subscription. By 1851 the college was built and opened with two faculties — science and medicine (now including a school of pharmacy and a dental-surgery department); in 1873 the new college buildings were constructed, and the number of students was 1004; in 1891 they numbered 811, besides 439 evening students, and there were about eight hundred families.

In 1874 Charles Clifton of Jersey City, United States, bequeathed his residuary estate (£21,571) for the extension of the department of mechanical arts and engineering, and in 1876 Charles Bover of Manchester left to it by will £100,243. Other benefactions and subscriptions produced over £260,000 for its development and endowment. The idea of a university at Manchester, which had been mooted so long ago as 1641, and revived in 1789 and 1806, was at length carried out. In 1880 the Victoria University was fairly launched, though at first without the power of granting degrees in medicine and surgery. This last restriction was removed in 1883. The senate consists of the principal and the professors for the time being. The characteristic features of the university, as compared with other British universities, are these: (1) the university is open to all candidates who have passed certain examinations only, but it also requires attendance on prescribed courses of academic study in a college of the university; (2) the constitution of the university contemplates its ultimately becoming a federation of colleges; but these colleges will not be situated like those of Oxford and Cambridge in one town, but wherever a college of adequate efficiency and stability shall have arisen. Besides Owens College, the Yorkshire College at Leeds and University College, Liverpool, have been already admitted, together with the several colleges of the University of Manchester. Women was incorporated with it. Women enjoy full rights of studying, except the right to use the libraries. There are two permanent fellowships, two others not endowed, and from thirty to forty scholarships and prizes. Many of these last, together with the professorships, are open to competition by women as well as men. See Owens College: its Foundation and Growth, by Joseph Thompson (Manchester, 1886).

Owen Sound, a town and port of entry of Ontario, at the head of Georgian Bay, 122 miles by rail NW. of Toronto. It possesses a deep sheltered harbour (12 miles by), and has a large trade in lumber and grain, being a considerable manufacturer of furniture and wooden wares, machine, woollen goods, &c. The Canadian Pacific steamer leaves here for Port Arthur. Pop. (1891) 7407.

Owl (Strigey), a sub-order of birds, consisting with two other sub-orders—the Pandionides (ospreys) and Falcones (hawks, falcons, and eagles)—the order Accipitres or Raptures (birds of prey). The owls, generally spoken of as the nocturnal birds of prey, have long been given the name of owls because of their characteristic size of the birds is very large; the skull is broad, and the cranial bones are highly pneumatic; the facial region is flattened; the beak is short, curved, strong, and sharp, never turned to its base are bristles covering, more or less completely, both the cere and the nostrils. The eyes are very large, directed forwards, google-like, only slightly movable on account of the bony sclerotic plates being fixed firmly to one another and to the orbit; the upper eyelid is very large, and is the one principally concerned in closing the eye; both eyelids are ciliated with barbed plumes and have a broad, thin, bare margin; the third eyelid, or miltirating membrane, is conspicuous; the iris is unusually broad, and is capable of being greatly expanded and contracted; the pupil is oval with the long axis perpendicularr. A disc of feathers surrounds the eye, either completely or partly, and is supported by a ruff made up of rows of small, much-curved feathers inserted into the skin by stiff shafts. The ear is peculiar and variable; it has a varying number of tufts, sometimes large of large size, and sometimes provided with a special flap of skin or operculum. The head often bears a pair of tufts known as feathered horns. The neck appears short, sometimes extremely so. The body, though really small, is apparently full, being covered with soft downy feathers without after-shafts. The plumage is generally spotted or barred with different shades of brown and yellow. In nearly all owls two different phases of colour, a darker and a lighter, can be distinguished, the two phases being often observed in different individuals of the same bird. The tail is generally short and long and loose. The tail is usually short and even, or slightly rounded. The oil-gland is destitute of the usual circle of plumes. The legs are not long, and are almost completely feathered. The toes are often covered with feathers, and are always provided with a small, thick, strong talon or claw. The fourth toes can be opposed to the second and third. The mouth is very wide; the gullet is large; there is no crop; the stomach is large, roundish, and somewhat compressed; the intestine is short, and has two wide ecaes connected with it. The indigestible portions of food are regurgitated in the form of pellets as in other Accipitres.

Owls range over the whole globe, from the extreme
polar regions to the remotest oceanic islands. No birds are more cosmopolitan in their distribution. In their habitat they are generally nocturnal; their flight is not rapid, though occasionally sudden or dashing; but their eyesight is very acute, as is also their sense of hearing. They are either solitary or live in pairs, and although so often regarded with superstitions aversion and animosity, they are nearly always harmless and very useful birds. Their food consists of small mammalians, birds, and reptiles, especially nocturnal lepidoptera; and some species prey on fish, either habitually or occasionally. They pounce upon their prey noiselessly, and, striking their talons into it, kill it and carry it off. Small animals may be carried in their bill, and are swallowed whole; larger animals are carried through the mouth. The disgorged pellets of indigestible materials—bones, fur, and feathers—produce a characteristic fetid odour near the owl's abode. The examination by Dr Altam of remains found (communicated to the German Ornithologists' Society) gives a good idea of the food and utility of the three commonest species of British owls.

The nesting habits of owls vary considerably. The nest is rarely made of twigs and grass, in holes of trees, crevices of rocks, dark corners of buildings, or beneath piles of stones; and the nest is so frail that it is all, or only the forsaken one of some other bird. The eggs are usually white, either pure or yellow, or blue tinted, and almost spherical, commonly four to six in number, but some species lay eight or ten, others not more than two. The young remain in the nest, and are helped by their parents for some days after going abroad. Some owls are diurnal in habit, and these have more compact plumage, smaller ears, and incomplete discs; but the habits of owls in general are too little known to allow of many general statements being made regarding the adaptation of structures to particular habits. Though the small and un-specialised ear is said to characterise diurnal species, it is found in the eagle-owl, whose habits are nocturnal. Unfeathered legs are sometimes associated with fishing habits, and are sometimes with the night-fishers; the eyes are large, and being bewilded and rendered helpless by the unaccommoded glare of the daylight. When surprised, owls hiss like a cat and make a clicking noise with their bills; some have a harsh shrieking cry, others a not unmusical hoot.

The Strigidae are a family of owls, which includes a large number of species common to both families. The genus Strix includes the only one species (P. badius), which ranges from the eastern Himalayas to Burma and Pegu, and is also found in Ceylon, Java, and Borneo. This genus possesses a number of characters common to both families, and is really an intermediate form belonging properly to neither. A species from Madagascar, described by Alphonse Milne-Edwards under the name of Helydota soumagni, has been placed in this sub-family.

Among the Strigidae the Tawny Owl, Wood-owl, Ivory-owl, Brown Owl (Strix striolata or aluco, or Syrnipnus aluco) is a very common British species. It is found chiefly in wooded parts of England, and in the midland and southern districts of Scotland.
but also as far north as Caithness and the inner Hebrides. Its cry is hoo-hoo, or tu-whit, tu-whoo at night makes it easily recognised. Although a species deserving to be preserved, it is rapidly declining in numbers. It ranges from the southern parts of Scandinavia through temperate Europe, in some parts of which, however, it is very local, to Asia Minor, Palestine, and Barbary. The Snowy Day-owl, the Harfang of the Swedes (Strix or Surnia nyctea or Nyctea scandinavica), is a circum-polar bird, breeding chiefly within the Arctic Circle, and inhabitants of Greenland and Iceland. Its home is on the fields of Lapland, the tundras of Russia and Siberia, and the prairies of Arctic America, where it feeds on lemmings and other small rodents, sometimes on ptarmigan and willow-grose, and even on the Arctic hare and on fish. In Shetland, where it has been known to breed, forced from its home by exceptional cold, and in other parts of the British Islands it is found generally in solitary, stony, and elevated places, preying chiefly on sandpipers. It is a diurnal bird of large size and vigorous build, with a perfect flight, with strong limbs, toes completely feathered, and long talons. Its white plumage, generally marked with dusky-brown spots, distinguishes it from every other owl. The Long-eared and Short-eared Owls of Europe, Asia, and America (Asio otus and A. accipitrinus), which are also common British species, have the ear peculiarly developed, the opening on one side looking upwards, and on the other downwards. The Long-eared owl, which frequents wooded localities, is about the size of the Barn-owl, and generally carries its horns erect; while the Short-eared, known also as the Woodcock-owl, from the coincidence of its time of appearance, prefers moors and open country, and carries its horns depressed. The speciation of ear-structure is carried to its greatest known limit in Tengnalm's owl (Nyctala tengnalmia), a rare visitor to Britain from the northern regions; in it the bones of the head are developed differently on each side. The Eagle-owl (q.v., Bubo maxima), the Little Owl (Athene noctua), the Hawk-owl (Surnia fuscata), and the very small Scops-owl (Scops ginn) are the only other species recorded as found in Britain, and these are all very rare. Of foreign species belonging to this family one of the most noteworthy is the Burrowing Owl (Spatdylor or Athene cucurullaria) of America. On the prairies of North America it shares the burrows of the prairie dog and other mammals, while on the pampas of South America it lives in the holes of the viseach, a ground squirrel, and bacteria, and even a hole for itself, which is often invaded by rattle-snares. Another interesting species is Pel's Fish-owl (Scopelia peli).

Oxalic Acid. H₂C₄O₄ + 2H₂O, occurs in colourless, transparent, oblique, rhombic prisms, which have an acrid taste and turn gummy in nine parts of cold water, and much more freely in boiling water. When heated to 212° (100° C.) the crystals lose their two equivalents (or 28.5 per cent.) of water, and the residue, consisting of the anhydrous H₂C₄O₄, becomes opaque. When the crystallised acid is rapidly heated to about 200° (149° C.), or when it is warmed with strong sulphuric acid, it is decomposed into carbonic acid and carbonic oxide gases, and into water. Oxidising acids, such as bimoxide of manganese, peroxide of nitric acid, &c., convert oxalic into carbonic acid, and on this property is based a good method of determing the commercial value of the black oxide of manganese, one of the most powerful of the organic acids. Exeps carbolic acid and many other acids from their salts. The acid itself, which, like the soluble salts, is poisonous, is very widely diffused throughout the vegetable kingdom, sometimes in the free state, but more frequently as a salt of lime, as in rhubarb and many lichens. In the animal kingdom it never occurs except in minute quantity, and in combination with lime. It is produced by the action of either caustic potash or nitric acid upon some natural compounds of natural occurrence. Its most common mode of preparation is by the oxidation of starch or sugar by nitric acid. The organic compound and the nitric acid are heated in a flask till all effervescence has ceased, after which the solution is evaporated, and the oxalic acid separates in crystals on cooling. The most important salts are the oxalate of ammonia, (NH₄)₂C₄O₄ + H₂O, used as a test for lime, and the binoxalate of potash or salt of sorrel, K₂C₄O₄ + H₂O, also known as essential salt of leaven, and which is popularly used for removing ink-stains or for cleaning brass.

The best test for this acid is the production of a white precipitate (of oxalate of lime), on the addition of any soluble salt of calcium. The precipitate is insoluble in water, in solution of potash, and in acetic acid, but dissolves in the mineral acids. A solution of nitrate of silver also gives a white precipitate of oxalate of silver, which explodes when heated.

In consequence of its employment in cotton-printing, bleaching straw, &c., oxalic acid is more accessible to the general public than many other poisons; and on this account instances of suicide from the swallowing of this acid are by no means uncommon. Cases of accidental poisoning, moreover, sometimes occur from its being sold by mistake for Epsom salts. Large doses destroy life rapidly. With the view of converting the free acid in the stomach into an insoluble and inert salt, chalk, whiting, or lime-water, with full drachms of milk, should be administered with the least possible delay. Salt of sorrel is almost as poisonous as the pure acid.

Oxalidee, or Oxalidaceae, a natural order of exogenous plants, allied to Geraniaceae; including large-leaved plants, shrubs, or trees, generally compound alternate leaves; calyx of five equal persistent sepals; corolla of five unequal unguiculate petals, spirally twisted in bud; ten stamens; the ovary five-celled, with five styles; the fruit a capsule of five cells opening by five valves, or more rarely a berry with five one- or many-seeded.
cells. Temperate North America and the Cape of Good Hope may be said to be the headquarters of the order. The herbaceous parts of almost all the species are distinguished by a strong acidity, which is owing to the presence of oxalate of potash; some, however, are bitter and slightly stimulating. The fruit of some is pleasingly acid and cooling—as Carambola—and reputed to be antiseptic and antiscorbutic. The tubers of several of the typical genera (Oxalis) are eaten, and contain a considerable quantity of starchy matter. The leaves of all the species are more or less sensitive. The Wood-sorrel (O. acetosella) is a native of Britain, and one of the most elegant of the wild flowers, carpeting woods and shady places with its bright trifoliate leaves and white or rose-tinted flowers. Its leaves, resembling as they do those of the clover, have led to the supposition that it may be the true Shamrock (q.v.). The plant, which is antiscorbutic and refrigerant, is widely distributed through Europe, Russian and central Asia, and across Southern America. It is most used in medicine on the Continent; and in Lapland, when very abundant, it is the favourite herb of the inhabitants. The expressed juice of the petioles is binoxalate of potash. Twenty pounds of fresh leaves yield about six pounds of potash, obtained after boiling the plant in pure salt. — Salt of Sorrel and Essential Salt of Lemons (see Oxalic Acid).

The preparation is carried on mainly in Switzerland and Germany; not, however, exclusively from this species of Oxalis, but from several other species of the same genus and of the true sorrels (Ranunculus), which contain the same salt. The numerous species of Oxalis strongly resemble each other in their general appearance and properties. Several of them, such as O. crenula and O. tuberosa, natives of Peru and Bolivia, and O. Doppia, a Mexican species, are cultivated in the countries for the sake of their tuberous roots, which are edible. These species have all been recommended for culture in Britain as substitutes for the potato, but their produce is too meagre to deserve attention; besides, the plants are constitutionally adapted only to the most suitable parts of England. Averrhoa bilimbi, or Cunnemuller-tree, indigenous to the East Indies, and now cultivated in some parts of South America, produces a green fleshy fruit of the shape and size of a small cucumber, which is esteemed for its grateful and juicy when ripe. This tropical fruit is also pickled.

Oxaluria, the occurrence of crystals of oxalate of lime in the urine (q.v.).

Oxenford, John, dramatist and critic, was born in Camblerwell in 1612, and was originally educated for the bar, but early turned to a life of letters, made himself familiar with French, German, and Spanish literature, and soon made his name known by admirable translations of such notable books as Lessing's Dichtung und Wahrheit, and Zecher's Conversations with Goethe. For his last thirty years he was dramatic critic for the Times, and his criticisms were ever characteristic of the genial kindness of his nature. He was a fluent and graceful writer, yet his original work was often rather than distinguished, his powers being wasted in a critic. His Illustrated Book of French Songs (1855) showed a dexterous mastery of the lighter forms of verse. He wrote many plays, among them The Dice of Death, the Reigning Favourite, the Two Orphans, as well as the libretto of The Libell of Killarney, and one farce at least, Twice Kilted, that became widely popular. He died February 21, 1857.

Oxenstierna, Henry Nutcombe, theologian, was born at Harrow, November 15, 1829, and educated at Balliol College, Oxford, taking a classical second-class in 1850. He took orders in 1854, and held various curacies, but entered the Roman Catholic Church in 1857. He was for some time at St. Edmund's College, Ware, and master at the Oratory School, Birmingham. He died March 23, 1888.

Oxenstierna translated Dollinger's First Age of the Church (1856), and Lectures on Re-union of the Churches (1872), also vol. ii. of Hefele's History of the Councils of the Church (1878); and, besides frequent articles in the leading reviews, the following learned works came from his pen: Catholic Doctrine of the Atonement (1865); Catholic Eschatology and Universalism (1876); Short Studies in Ecclesiastical History and Biography (1884); and Short Studies on the Scriptural and Evidential Basis of Revelation (1887).

Oxenstierna, or Oxenstien, Axel Count, Swedish statesman, was born at Fårö, north of Stockholm, 16th June 1833. He was originally educated for the church, and studied theology as well as jurisprudence at Rostock, Jena, and Wittenberg, and, although he entered (1862) the public service of his country, he continued for three years to take a deep interest in religious questions, and laboured zealously for the extension of the Protestant doctrines. Charles IX. despatched him in 1606 as ambassador to the court of Mecklenburg and made him senator in 1609. Having displayed great prudence and astuteness, he was engaged in the disputes between the Livonian nobles and the town of Reval, he was appointed by Charles—now in prison—guardian of the royal family and head of the regency. On the accession of Gustavus Adolphus (q.v.) in 1611 he became chancellor, and in 1613 acted as minister-pleni-potentiary in the negotiations for peace between Sweden and Denmark, and in 1617 in those which terminated hostilities between Sweden and Russia. In 1621, on the departure of the king for the Polish war, Oxenstierna was charged with the administration of affairs at home, but five years later was summoned to act as governor-general of the conquered districts in Prussia. In 1629 he concluded peace with the Poles on highly favourable conditions. Although he strongly opposed the desire of Gustavus to take part in the Thirty Years' War, yet, when he found that the Protestant sympathies of the king were irresistible, he supported his master most faithfully and ably; Gustavus in return charged him with the difficult business of managing the diplomatic relations of Sweden. After the king's death it was Oxenstierna who not only kept the Swedish armies together, but sustained the Protestant cause and prevented it going to pieces on the jealousies of the German Protestant princes, displaying masterly diplomatic ability, great courage, resource, and moderation. Having in four or five years reorganised the Protestants and reanimated their courage by gaining French and Dutch assistance, he went back to Sweden (1630). He had already drawn up a constitution, which the estates accepted and ratified. After having served for some years as the duties of chancellor, adding to them those of guardian to the young queen Christina, who, however, did not accept the advice of her father's wise friend and counsellor as it beemed her. Oxenstierna continued to direct the policy of Gustavus in his will till his death. When Westphalia in 1648 put an end to the war. He humiliated the Danes and forced them to sign the treaty of Brömsebro (1645), and opposed the adhesion of Christina and the succession of Charles X. This king, however, was detained in office until he died, 28th August 1654. See Lundblad's Svensk Plutarch (2 vols. Stock. 1821); Fryxell's History of Gustavus Adolphus; Geijer's History of the Swedes (Lond. n.d.) and Journal of Bulstrode White- locke (1772). His Writings and Correspondence
began to appear in 1888.—His eldest son Johan (1611–57) carried through several diplomatic missions, his greatest service being to act as Sweden's plenipotentiary at Osnabrück (1648). It was in a letter to this son, who felt himself unequal to the office, that the chancellor used the famous phrase, 'Nec habet, qui WiFiquit, quam parva sapienter regi mudus.' This aphorism is current, however, in an extraordinary number of versions (Notes and Queries, 7th July 1888).—The younger brother Erik (1624–56) was governor of Estonia (1640), and succeeded his father as chancellor of the kingdom.

Oxford. See CHRYSANTHEMUM.

Oxford, the capital of the county, the home of the university, and the seat of the bishopric of the same name, stands about the confluence of the rivers Cherwell and Thames, 82 miles (33 by rail) WNW. from London. The city, under the Act of 1889, is governed by a council, comprising a mayor, fifteen aldermen, and forty-five councillors, of whom three aldermen and nine councillors are elected by the university. Up to 1888 the city returned two members to parliament; since that date only one. Until about 1830 the area and population of the city remained almost stationary, extending only a little beyond the limit of the old city wall as reconstructed in the reign of Henry III, and very little beyond the area represented in Loggan's bird's-eye view (1675). But since then the city has grown rapidly, and the rural districts of St. Giles' on the north, St. Clement's on the west, Grandpont on the south, and Botley on the east have been covered with lines of close-built streets. Pop. (1801) 11,000; (1831) 25,700; (1881) 40,872; (1891) 64,714.

The topography of Oxford is simple in the extreme. The river Thames (locally called the 'Isis'), which has flowed from north to south, takes here a sharp bend to the east, and about a mile from the angle receives the Cherwell, flowing from the north, parallel with its former course. All the old part of the town stands in the rectangle thus formed by the rivers. The centre of the town is at a place called Carfax ('derived from quadrifurca, 'four-forked'), from which four main streets run to the four points of the compass. Taking in rotation these four lines of streets, we shall be able to pass quickly in review all the chief buildings and places of interest. North runs Cornmarket Street ('the Corn'), containing the Roebuck and Clarendon Hotels, past the latter of which is the entrance to the Oxford Union Society's rooms (the club, library, and debating-hall of the university), erected in 1823. At the end of Cornmarket Street is St. Michael's Church, the tower of which (c. 1070) is a characteristic specimen of Saxon masonry. Here formerly was the north gate of the city, the chambers over which (taken down in 1771) were used as a prison, and called the dungeon. From the end of Cornmarket Street, George Street runs west, containing the New Theatre (1886) and the High School for boys (1881); Broad Street runs east, containing Balliol, Trinity, and Exeter Colleges, the Ashmolean Museum, the Sheldonian (the University 'Theatre'), the Clarendon Building (used for the Clarendon Press till 1830, now as university committee-rooms), and the Indian Institute (library, museum, &c., for natives of India and members of the Indian Civil Service studying in Oxford, opened 1884). Broad Street was the place where the University Library was burnt (Ridley and Saffron on 16th October 1555, and Cranmer on 21st March 1556). The Martyrs' Memorial, a cross in their honour, was built in 1841, at the end of Magdalen Street, the continuation of Cornmarket Street. Beaumont Street leads west from this point, past the Randolph Hotel (built 1864), the Taylor Library (for modern literatures, founded by Sir Robert Taylor, built 1845), and the University Galleries (containing the Ruskin Drawing school, the Arundel Marbles, presented to the university in 1697, and other relics of classical antiquity, a valuable collection of paintings and engravings, and 190 original drawings by Michael Angelo and Raphael), to Worcester College. Thence northwards, by Walton Street, access is got to the University or Clarendon Press (removed to new buildings here in 1865), to St. Mary's Church (1888), to Port Meadow (an extensive flat ground beside the river, being the common of the freemen of the city), and the 'Upper River' or part of the Thames north of Oxford, and so to Gostaun, a ruined nunnery, famous as the burial-place of Fair Rosamond. Returning to the Martyrs' Memorial, the street leading north from Magdalen Street (so called from St Mary Magdalen Church), is St. Giles' Street, containing St. John's College and the Pusey House (a library and clergy-house, in support of Anglican principles, established 1884 in memory of Dr Pusey, and containing his library). In the Woodstock Road continuation of St. Giles' Street are the church of St. Aldobrand (Roman Catholic), built in 1875, the Radcliffe Infirmary (1770), and the Radcliffe Observatory (1795). In the Iffley Road continuation of St. Giles' Street are Somerville Hall (a ladies' college, 1879), the High School for girls (1884), and Wykeham Hall (a Church of England theological college of the intrinsic order of the Evangelical party, 1877). West.—Returning to Carfax, and taking another quarter of the city, Queen Street, continued by New Road, leads past the Castle (including the court-house and gaol) to the railway stations, and so along the Seven Bridges Road (across cuts from the Thames) to Cumnor.
Oxford

South from Carfax runs St Aldate’s Street, past the town-hall (built 1752), public library, corn exchange, and post-office (1881), St Aldate’s Church (rebuilt since 1863), Pembroke College, the colleges, the Reading-room to Chire College Meadow and Broad Walk, to Folly Bridge across the Thames. This bridge was rebuilt in 1815. Over the old bridge was a watch-tower (taken down in 1779) known as ‘Priar Bacon’s Study.’ From near Folly Bridge, for about a quarter of a mile north of the river, are moored the barges (see BARGE) of the university and college boat-clubs.

East from Carfax runs High Street in a graceful curve. In the High Street itself, or just off it, stand the buildings, in this order from Carfax: the old city market (1773), the Mitre Hotel (extant, as Dagville’s Inn, before 1470), the church of All Saints (built in 1706 from designs by Dean Aldrich), the new front of Brasenose, the University Church (St Mary the Virgin), where are preached the university sermons (including the ‘Hampton Lectures,’ q.v.), All Souls, University, and Queen’s Colleges, the Examination Schools (1829), with the Non-collegiate Students’ buildings, Magdalen College School (founded 1490), Magdalen College, and the Botanic Gardens (laid out in 1632). The stream flows through the Broad Walk to the Cowley. From this bridge roads lead to Cowley and Iffley, past the college cricket-grounds and the running-ground of the University Athletic Club. At Cowley is a college for army cadets, called the Oxford Military College, opened in 1876, and the Queen’s Barracks, the Barrack-rate of Christ Church into Merton Street, where are Corpus Christi and Merton Colleges. From St Mary’s Church, Catherine or Cat Street leads north, having on the west the Codrington Library (built about 1720 by All Souls College to contain the library of Christopher Codrington, and maintained by the college as a law library), and on the west the Radcliffe Library (built in 1737 as a library for medicine and natural science; since 1861 a reading-room in connection with the Bodleian); and farther on the Old Schools (including the Library Museum, or Divinity School) on the west, and Hertford College on the east. Past Hertford College a street leads to New College, Cat Street, after crossing Broad Street, is continued by Park Street, which leads northwards past Walliam College and the garden front of Trinity College to the University Museum, Keble College, and Lady Margaret Hall (a ladies college, opened about 1880). Here are the University Parks, laid out and kept up by the university. They contain the university observatory, erected in 1825, a Decoy pond with the football matches (Rugby, Association, Winchester, and other varieties of the game) of the university and college clubs. Here also is the new ground of the University Cricket Club, one of the finest in itself, and in its surroundings, in England. A walk leading from the Parks, east and south, is known as ‘Mesopotamia,’ being between two cuts of the Cherwell.

All Souls College was founded in 1437 by Archbishop Chichele as a chantry for the souls of those who had fallen in the wars with France. It remains still a college entirely of fellows; several of the fellowships have been let to the University of Oxford. The front quadrangle is practically as the founder left it; the fine chapel (consecrated 1442) contains a beautiful reredos, partially destroyed in 1577 and in 1694, but restored in 1876. The hall (built in 1720) contains some good portraits of former fellows, among them those of Sir William Blackstone, Reginald Heber, Sir Christopher Wren, Thomas Tanner, John Linsere, Jeremy Taylor, and Herrick.

Ashmolean Museum, the earliest public museum in England, built in 1862 to receive the antiques, &c. of Thomas Ashmole, and named after him. The original Ashmole’s collection was dispersed; the books and MSS. going to the Bodleian, the natural history specimens to the Museum, the anthropological (including curiosities brought home by Captain R. Murchison) to the Pitt-Rivers collection. The museum now contains British antiquities, antiquities from Cyprus, Egypt, &c.

Balliol College, founded about 1208 by Deveryngh Balhol, mother of the elder Balhol, king of the Albanians. The buildings are chiefly modern, the hall (1877) being a favourable example of recent Oxford building. This hall contains portraits of John Wycliff the Reformer, formerly master of the college; of Archbishop Tait; of Robert Browning, honorary fellow; and of Benjamin Jonson, poet. In the hall are paintings of the Sire William Hamilton, Colot, Parsons the Jesuit, John Evelyn, Robert Southey, Dean Stanley, Matthew Arnold, C. Swinburne, and Cardinal Manning were members of the college.

Bodleian Library (q.v.), founded in 1602 by Sir Thomas Bodley, in a room (built about 1469) over the Divinity School for the old library of the university, and augmented from Bodleian, Emmanuel, and Magdalen Colleges. Humphrey’s Library had been plundered by King Edward VI’s commissioners. The library has grown to be one of the great libraries of the world; it contains more than 30,000 MSS. and 6,000,000 volumes. It occupies the whole of the Old Schools (built 1618) of the university. The library contains a fine portrait of the founder. The picture-gallery attached is one of the best examples of a ‘picture-gallery’ of an ‘improved’ kind. The old ‘brazen nose’ knocker of Brasenose Hall, on the site of which the college was built, was (it is claimed) acquired in 1890, and is now found in the hall. John, Lord Herbert; Dean Milman, Barham, and F. W. Robertson were students.

Christ Church is both the cathedral of the diocese of Oxford and a college of the university. The cathedral was instituted in 1546 by King Henry VIII. in the old priory of St Frideswide (q.v.). This church contains many remains of Norman architecture (1120–90), and (it is claimed) some fragments of the older Saxon church. The college was founded by Cardinal Wolsey in 1525 as ‘Cardinal College,’ the priory of St Frideswide being suppressed by him; was remodelled by the king as ‘King Henry VIII.’s College, in 1532; and finally settled, as ‘Christ Church,’ in 1546. The hall and the kitchens belong to the Wolsey’s former building of the kind in Oxford, or even in England. The great quadrangle (‘Tom’ Quad.) begun by Wolsey was not completed till 1603. Peckwater Quadrangle was re-built in 1862 to 1865. The Oxford Museum of Antiquities (opened 1860) now contains ‘Great Tom,’ one of the largest bells in England, being the great bell of Oney Abbey recast (see BELL, Vol. II, p. 55). ‘The Broad Walk’ of clumps leading from the Museum to the Cherwell was planted by Van Foll (q.v.) in 1670, was long one of the finest avenues in England; but its glories have been lessened of late years by storms, the elm being unable to outlast two centuries. The library is a valuable one, especially by great Italian masters, with a few of the Dutch masters. The hall contains many portraits of eminent statesmen and divines by great painters, from Holbein to Gainsborough. The portraits of Philip II. of Spain, of Pedro the dramatist, John Locke, Sir George Cornewall Lewis, Dr Liddon, Gladstone, and John Ruskin are a few of the famous names of Christ Church men.
Merton College, founded in 1364 at Malden in Surrey, and transferred to Oxford in 1274 by Walter de Merton, Bishop of Rochester, was the first institution in Oxford organised as a college; and is therefore the type of which there has been a limitless existence at Oxford or Cambridge. The old quadrangle (‘Mob Quadrangle,’ 1278) and the library (1576) of this college are the most primitive college buildings in Oxford. The chapel (1341) is a fine example of building, with arcades and clerestory. The Members of Merton College have been remarkable benefactors to the university; Sir Thomas Bolley, who founded the university library, and Sir Henry Savielle, who was a benefactor of the college, are worthy of mention in this connection. Duns Scotus is said to have been fellow here; William Harvey, discoverer of the circulation of the blood, was warden; and other members were Bishops Hooper, Jewel, and Parkhurst; Anthony Wood, the great Oxford antiquary (buried in the ante-chapel, 1695); and Steele.

MUSEUM, the ‘New Museum,’ was built in 1837 to 1860, for the reception of the university medical and natural science collections, and the medical and scientific library of the Radcliffe trustees, and the accommodation of the university teachers in science. Large additions have since been made, particularly in the departments of chemistry, electricity, anatomy, and physiology. A new wing and additions in 1886 to 1888 form a remarkable archaeological collection of General Pitt-Rivers.

NEW COLLEGE, founded in 1379 by William of Wykeham, Bishop of Winchester. Walter de Merton’s college is said to have been the only college in Oxford, and was therefore known as ‘the college par excellence.’ Wykeham’s college was therefore known as ‘the new college;’ a name which it has retained to the exclusion of the name the founder gave it, ‘St Mary of Winchester.’ Wykeham founded a college to be a school to supply his Oxford college. The hall, chapel, cloisters, bell-tower, and other buildings were on a scale hitherto unknown in Oxford, and, except at Magdalen and Duisbury College, have had rivals. The gardens are very beautiful, and are bounded by the only perfect segment of the city wall. The best-known names of members of this college are Archbishop Warham; William Waynflete, founder of Magdalen College; Henry Cheiche, founder of All Souls; Bishop Ken; Sydney Smith; and Augustus Hare.

NEW INN HALL, founded about 1369, was closed in 1887. During the Civil War, when Charles I held Oxford in 1642, the royal mint was set up here, and the old plate of the college was coined for the king’s use.

Oriel College, founded in 1263, nominally by King Edward II, but really by Adam de Brome, his almoner, for the accommodation of students from the Welsh country, is called ‘Oriel,’ a house on the present site, whence it has its modern name. For a long time it was known as ‘King’s College’ (Collegeium Regale). The buildings are modern, the college hall with a tower, dating from the 16th century. The land, author of Piers Plowman, was, but erroneously, at one time believed to have been fellow here. Sir Walter Raleigh was probably commissor for a short time. In the first half of the 19th century Oriel College possessed a most distinguished body of fellows—Keble, Pusey, Thomas Arnold, Archbishop Whately, Cardinal Newman, Arthur Hugh Clough.

Pembroke College, erected in 1624 by Thomas Temple and Richard Owen, was originally out of Broadgates Hall, a most ancient place of academical study, in which Bishop Bonner, Beaumont the dramatist, and Sir Thomas Browne had been students. The name was given in compliment to the fine college buildings erected in Oxford in 1528, and is regarded by the University, and in hope of a godfather’s gift from him, which his death soon prevented. Members of this college (and hall) have filled the three Anglican primatial sees of Canterbury, York, and Armagh. The buildings were erected by Sir Thomas Temple in 1575. Sir Thomas Temple married Joane, daughter and heir of Sir John Luttrell, of Cloth-eaver, near Newcomb (Newcome, 1796). Dr Johnson was a student here.

QUEEN’S COLLEGE, founded in 1380 by Robert de Egestedel, chaplain to Philipus, queen of Edward III, was the arraignment of the queerness of the college; and at the same time being should be patronage of the college; hence its name, and ses of donations by queens of England when the college was in difficulties. The college was rebuilt in 1676, when the present quadrangle was erected. Queen’s College was a college for a short time; and other members were Cardinal Beaufort, Wyckerly, Addison, and Collany. The college retains the old ceremony of bringing in the ‘Brow’s Head,’ with the traditional song, on Christmas Day.
ST ALBAN HALL, founded about 1290, was united to Merton College in 1882.

ST EDMUND HALL, founded about 1280. Queen's College appoints the provost, Thomas Hearne, the anti-
querry, was long resident here.

ST JOHN'S COLLEGE, founded in 1555 by Sir Thomas White. The chapel, hall, entrance tower, and part of the street front were built in 1510 by Ralph Taylor, Richard Nevile, Sir Kenelm Digby, and De Quincey were members.

The university of Oxford is a corporation under the title of 'the chancellor, masters, and scholars of the university of Oxford.' It consists of a body of graduates (masters of arts and graduates in law, medicine, and divinity) who are the governing members of the corporation, and of a body of undergraduate bachelors of arts) who are 'in statu pupillari,' that is, subject to the government of the officers of the university and without voice in university business. The statutes by which the university is governed are partly the code promulgated in the chancellorship of Arch-

SHELDONIAN THEATRE, built in 1669 by Archbishop Sheldon for the holding in it of the great university degree ceremonies. These had hitherto been held in St Mary's Church. Sheldon built the curtained closets for spectators (in 1652 the undergraduates had to be kept in order by soldiers of the garrison) often scandalised those who had regard to the sacred character of the building. The 'act' of the college houses, which was granted (the 'doctors' degrees granted during the year were supposed to be completed by 'inception') is now superseded by the Elocution, in which prize compositions are recited (among these, I.), honorary degrees are con-
tinned, and a Latin oration delivered.

TENNENT COLLEGE, founded in 1554 by Sir Thomas Pope. The library is part of Durham College which stood here (see DURHAM); the hall dates from 1630; the chapel, with its fine carved cedar, from 1684; the garden quadrangle was built 1665-1728; and large new buildings were added in 1837. The 'Lime Walk,' planted in 1713, is the feature of the garden. Keble Hall, on Broad Street, near the college, is one of the close halls.

UNIVERSITY COLLEGE, founded in 1872 by Sir John Hope. The college is a great power in Oxford in 1880-88, when its master, Obadiah Walker, was the chief agent in the New University.' The college was founded by King Alfred, destroyed in the Danish invasion.

By a later effort of imagination King Alfred was said to have founded University College in 782 A.D. University College was a great power in Oxford in 1880-88, when its master, Obadiah Walker, was the chief agent in the New University.' The college was founded by King Alfred, destroyed in the Danish invasion.

By a later effort of imagination King Alfred was said to have founded University College in 782 A.D. University College was a great power in Oxford in 1880-88, when its master, Obadiah Walker, was the chief agent in the New University.' The college was founded by King Alfred, destroyed in the Danish invasion.

WADHAM COLLEGE, founded by Dorothy, widow of Sir Nicholas Wadham, in 1613, on the site of the old Austin Friary. The buildings of this college perhaps owe something to the labours of the friars. The college buildings are an exquisite specimen of Jacobean work; the street front in particular is one of the prettiest bits in Oxford. Admiral Blake was a student here, and his portrait hangs in the main hall. The Royal Society met here in meetings in the rooms of Dr John Wilkins, warden of Wadham.

WORCESTER COLLEGE, founded by Sir Thomas Cookes of Worcestershire in 1420, and re-founded in 1714, in Gloucester Hall. Gloucester Hall had in 1590 succeeded Gloucester College, a college for Benedictine monks, founded in 1283, dissolved at the Reformation. Each monastery had its row of cells, and on one side of Worcester College there was a quadrangle, each with the coat of arms of its monastery carved in stone over the door, is one of the most interesting bits of old Oxford. During the earlier part of Eliza-

beath's reign Gloucester Hall was filled with Roman Catholic students, their tutors being graduates who had been ejected from their fellows in universities for refusing the oath of allegiance. In the 17th century there was for some time a project to find here a college for the education of clergy of the orthodox Greek Church. The Lieutenant, Sir Kenelm Digby, and De Quincey were members.

The earliest historical notices of Oxford show also its importance in early times. In 912 A.D. the Saxon Chronicle records that, on the death of Ethelred, Edward (the son of Alfred) took possession 'of London and Oxford and all the lands obedient to those cities.' The remarkable Castle mound,
new shamedly included in the precincts of the county gaol, was heaped up at this period, being part of the great system of fortifications which were then raised against the Danes. During the troubled years which follow Oxford is frequently mentioned in the Domesday Survey, especially in the western counties of Wessex rendering it important as a citadel against invasion, and as a place of parley between Danes and Saxons. It may be inferred that at the Norman Conquest Oxford offered a stubborn resistance to the invader (1) from the great number of "warriors" who were recorded in the Domesday Survey; and (2) from the vastness of the work erected by the conqueror's governor, Robert Doyley, to overawe the city and district. Two portions of this work remain, the tower (now of St Michael's Church) which commanded the approach to the assailable North Gate of the city, and the great keep of the Castle (now in the precincts of the gaol). In the contest for the crown between the Empress Maud and Stephen (1142) Oxford was again a place of capital importance, Maud taking refuge in Oxford when driven from London, and escaping over the frozen Thames by the custody of the castle, in order to surrender to Stephen after ten weeks' siege. Here in 1258 the "mad parliament" enforced on Henry III. the scheme of reform known as the Provisions of Oxford (see Montfort). From this date Oxford as a town censes to be of national importance, except for a few years in the heat of the great Civil War, when Charles I. made it the centre of his operations, the station of his court, and the meeting-place of the parliament which he had brought together in opposition to that 'Long' one at Westminster.

But, at every time when Oxford, as a city, was losing its political and strategic importance, there was growing up within it a distinct, and destined often to be a hostile, corporation which was to make it for centuries the intellectual capital of England. The word 'university' implies now a corporate body of teachers and students, established for the pursuit of the higher branches of learning, endowed with privileges and protected by charters granted by sovereign powers; and we find by the end of the 13th century and the beginning of the 13th a corporation of this kind established in Oxford. Some years before the above date, the corporation had only the official recognition of a guild of teachers with their pupils which was already in existence in the city; and a guild of this kind must, in its turn, have been the development of accidental, and perhaps temporary, assemblages of teachers and students. The beginning of the university of Oxford is therefore to be carried as far back as the earlier third of the 12th century; Thibaut, d'Estampes (Theobaldus Stampensis) about 1120, and Robert Palteau in 1135, being recorded to have taught in Oxford. The university, thus begun under Henry I. (who in 1116 built as a royal residence Beaumont Palace in the north suburb of Oxford, in which palace Richard Coeur de Lion was born in 1157), rapidly grew in numbers and in prestige; and by the beginning of the 13th century was of such interest that no one was interested in its fortunes, its scholars numbered perhaps by thousands and not by hundreds, and the fees between it and the town occasionally events of almost national importance. Teachers and scholars in this early university were of the secular clergy; they lived and taught ('in locis') and lecture-rooms ('schools') hired from the "chanoines"; and discipline was practically non-existent.

The fame of the university attracted to Oxford the four great orders of mendicant friars immediately after their arrival in England, the Dominicans (Black Friars) in 1221, the Franciscans (Grey Friars in 1224), the Carmelites (White Friars in 1225, and the Austin Friars in 1268. The friars, unlike the older orders of monks, who had stood aloof from secular learning, threw themselves with enthusiasm into the studies of the university; and the 'schools' in their convents and their lecture rooms later constituted one of the principal elements in the educational system of the university. That Oxford can boast the greatest names in mediæval learning and legend, Roger Bacon and Friar Bungay, is due to these conventual schools. So threatening did the supremacy of the friars become that the university in the early 13th century had to fight with them to retain the control of its own education (see the Rev. H. Rashdall's paper on 'The Friars Preachers versus the University' in the Oxford Historical Society's Collections, vol. ii. 1890).

The intellectual triumphs of the friars kindled the spark of emulation in the older monastic orders, and in their turn began to found conventual schools at Oxford for students of their own body. The Benedictines had four colleges in Oxford: Gloucester College, founded in 1283, part of whose buildings are now in Worcester College; Durham College, founded in 1312, now part of New College; Trinity College; Canterbury, founded in 1363, now taken into the site of Christ Church; and St Mary's College, founded in 1435, now a dwelling-house belonging to Brasenose. For the Osterclens St Bernard's College was founded in 1237, and parts of this building are still found in St John's College.

The introduction into the university of the conventual system, with the severity of its discipline, the interpenetrating stimulus of its common life, and the efficiency of its personal tuition, suggested a change of Oxford and university procedure which was to effect in time an entire revolution in its form. In 1264 Walter de Merton conceived the plan of bringing together into a common home a number of secular students, engaged in academic studies but subject to something like conventual discipline. In 1274 he moved his college (which he had established at Malden in Surrey) to Oxford. Two other institutions, which had been founded in Oxford at a slightly earlier date, soon, under the influence of the new idea, took the shape of Balliol and University Colleges. By 1285 ten colleges had been formed, and these have lasted as colleges on their original plans; only New College, Magdalen, and Wadham's Cardinal College (afterwards reconstituted by Henry VIII. as Christ Church, with a fraction of its former endowment).

The Reformations of religion, and the dissolution of the monasteries which it carried with it, destroyed half the glory of Oxford. Two abbeys, five friaries, and five monastic colleges ceased to exist; and the western and south-western quarters, which had contained the finest buildings of the city, became heaps of stones out of which the present churches of the quarter were formed. During the Romanist reaction under Queen Mary something was done to repair the loss thus inflicted; Trinity College in 1554 and St John's in 1555 restoring to Oxford Durham College and St Bernard's College. Jesus College, founded nearly twenty years later, in Elizabeth's reign, was the first of Protestant colleges. The more settled times of the early Stuarts patronised the gown more liberally; Wadham College coming in 1613, Pembroke in 1624. Then came the great catastrophe of the Civil War, and learning and the encouragement of learning ceased. In the middle years passed since the foundation arose in Oxford, in Sir Thomas Cookes' Worcester College; and, except for the abortive attempt (1740-1818) to erect Hart Hall into a college, that example found no imitator till our own times, when the foundations of Keble College in 1870 and of Hertford College in 1874, followed
by the transference to Oxford of Mansfield College and of Manchester New College (though these two colleges are not incorporated in the university), henceforward to the new life which has begun to thrrob alike in the Anglican Church and in Nonconformity.

In Elizabeth's reign, and still more under the Stuarts, we have to mark a very strong desire on the part of the supreme power to compel all students to the new life which has begun to thrrob alike in the Anglican Church and in Nonconformity.

The following six features the university of Oxford stands in marked contrast to universities not only in England but the simplest nation in Europe. Before a person becomes a member of the university he must first of all become a member of one of the twenty-one colleges or two halls; and the moment he ceases to be a member of one of these societies his actual membership of the university is also terminated. The university and the Oxford undergraduate is not left as a unit in a great body of two or three thousand, but is made a member of a much smaller body of perhaps eighty to two hundred members, and is therefore subject to closer personal scrutiny and to stronger influences of character than would be possible in a large body of men differing so materially. It is true that the influence of this common life is partially discounted in the case of students from the public schools, where similar influences have already formed their character; but in the case of students from small schools or solitary houses the vigorous social life of a good college is wonderfully efficacious in converting the raw, indolent, or morose boy into the frank, self-reliant, and sociable man. (2) The Fellowship System. Formerly every first-class man (and many second-class) was treated with official courtesy and respect, and found a place in the college, by the common entrance examinations, with his own title of 'Reader.' (4) The Discipline. The discipline of Oxford is much stricter than that of any university outside England. Within college the government of the college deans, without college the vigilance of the provosts and their deputies, repres disorder and immorality. Such as is the waste of young lives in Oxford, no one who has known a laxer discipline can refuse to recognise that if a man goes to the bad in Oxford he does it of his own wilful and obstinate choice. (5) At the same time, Oxford must be marked for the excessive severity of its regulations. The ordinary common life of the colleges has this disadvantage, that it requires considerable force of character for a poor student to live in proportion to his poverty; there being every inducement for a man of weak character to live after the fashion of his fellows and to become careless. Hence the son of a man of £400 a year often spends during his course at the rate of the son of £4000 a year, and begins his after-life under a heavy burden of debt. And lastly, amusements of different kinds, football, rowing, cricket, tennis, billiards, card-playing, debating, the theatre, to say nothing of the baser kinds, such as betting, wines, worrying rats and rabbits, are thought of, talked of, and pursued by many undergraduates till barely an hour a day in the eight weeks of term is left for any serious or
Oxford

...for the honours degree the candidate may choose one or more of the schools of—classics (officially termed ‘Literae Humaniores’), including not only the languages but the history and philosophy of Greece and Rome, and such other branches of modern learning as may be considered suitable for the subject; history, law, theology, oriental languages. Of these the most coveted distinction is the First in ‘classical granta,’ traditionally the chief Oxford school, for which most scholars and exhibitioners are required to read, and by examination in the subjects of which many of the few open or ‘prize’ fellowships are awarded.

The traditional ‘double first’—i.e. a first-class in classics and mathematics, when there were no moderations and only these two final schools, such as was won by W. E. Gladstone in 1831 and by Dean Liddell in 1838—is now forgotten; and as many as three, four, or even five firsts are obtained without bringing the successful candidate much reputation in the university, or even a fellowship. Candidates entering for an honour school and failing to get honours may be either ‘ploughed’—i.e. rejected entirely and ‘gulled’—i.e. allowed a stage in the pass degree. If a candidate in any school desires of his own accord, he can ‘scratch’—i.e. remove his name from the list of candidates.

The following list, compiled from the honours lists of 1890, exhibits the distribution of candidates among the honour schools and between the four classes in each school:

A comparison of the above table with the list of professors, lecturers, and demonstrators yields the ridiculous result that to produce twenty-six candidates graduating in honours in science the university employs a staff of twenty-seven teachers, and that those require the assistance of several college lecturers.

The number of persons who graduated B.A. in the academical year 1889-90 was 597. The degree of M.A. is obtained by keeping the name on the books for three (or four) years from the date of B.A., paying quarterly dues, and by paying graduation fees. The number of M.A.'s taken in 1889-90 was 421. The University of Oxford grants also the degrees of bachelor and doctor in divinity, law, medicine, and music. The exercises for degrees in divinity are merely formal, but the fees paid for these degrees are considerable. The bachelors' degrees in law, medicine, and music are awarded after examinations which have been brought up to the standard of those professions, but for the most part candidates study for them outside the university.
Oxford

683

Universities, on the production of approved theses. In the academic year 1889-90 the following persons graduated: In divinity, B. D. 13, D. D. 7; in law, B.C.L. 11, D. C. L. 2; in medicine, M. B. 9, M. D. 11. In music, B. Mus. 1.

The university, on the initiative of the Hebdomadal Council, from time to time confers honoris causa the degrees of M. A., D. C. L., and D. D., the latter by custom being always voted to members of the university who have been raised to the episcopal bench. The number of these 'honorary degrees' in the academic year 1889-90 was as follows: Hon. M. A. 1; Hon. D. C. L. 7; Hon. D. D. 5.

All ordinary degrees require that candidates should have kept a specified number of terms by having their names on the books of some college or hall or of the non-collegiate students. For the degree of B. A. it is further required that the candidate should have resided in Oxford during twelve terms. In the academic year there are four terms—Michaelmas term (October to December), Hilary or Lent term (January to March), Easter and Trinity terms (the latter beginning the day after the former closes, April to July). The first two are kept by six weeks' residence, the last two by three weeks' residence in each, the latter number of terms of residence being for eighteen weeks in the year. The colleges, however, under ordinary circumstances, require an undergraduate to reside eight full weeks in each term (counting Easter and Trinity as one term)—i.e., twenty-four weeks in the year.

The number of undergraduates is now much too large to be accommodated within the walls of the colleges, and most colleges have undergraduates residing outside the college in lodgings in the town. They are still, however, strictly under the control of the university and the college. (1) No undergraduate is allowed to lodge in a house nor with a landlord who has not been licensed by the university, a provision which partially guards against unsanitary lodgings and overt scandalous conduct, but immensely increases the expense of lodgings; (2) if the undergraduate goes out or comes in after 10 P.M. the fact is supposed to be noted in the gate bill which the landlord has to send weekly to the college. In October 1890 there were residing in lodgings 637 undergraduate members of the colleges and halls and 211 non-collegiate students.

Since 1868 there has been in Oxford a body of students not members of any college or hall, styled formerly 'unattached students,' but latterly 'non-collegiate students.' These reside in licensed lodgings; have a building provided by the university in which they attend lectures and meet their tutors; are under the disciplinary control of a censor, as the students of a college are under the control of their dean; and are supervised by a board of delegates, in the same way as the students of a college are by the head and fellows of their college. Under a statute of 1882 it is possible for a member of congregation to open a 'private hall,' of which he is the 'licensing master' for the residence of academic students. These private halls act elastically as a limbo to which, in preference to leaving the university altogether, students who have been rejected by or ejected from the colleges betake themselves.

The number and disposition of the fellows and undergraduate members of the university in 1891 are shown in the following table:

</table>

In this table it must be noted that in the column of commoners none are reckoned who matriculated before 1886, and that to ascertain the number of commoners in actual residence about five per cent. must be struck off the numbers given. At Merton College the scholars are called 'postmasters,' at Magdalen College, 'scholars'; at Christ Church, the fellows are called 'students,' and until 1877 the scholars were called 'junior students.' Christ Church, being a cathedral as well as a college, has also an ecclesiastical foundation of six canons.

Oxford is fortunate in having been described from the points of view of its different interests in several attractive handbooks: Rev. C. W. Bosan's 'Oxford City,' in the 'Hinton's Towns' series (Longmans, 1887); Dr. Brodick's 'History of the University of Oxford,' in the 'Epochs of Church History' series (Longman, 1886); Rev. E. Marshall's 'Oxford Diocese,' in the 'Diocesan Histories' series (S, P.C.K., 1882); and The Colleges of Oxford: their History and Traditions, edited by A. Clark (Methuen, 1891). Messrs. Parker's Handbook for Oxford is an admirable guide to the architectural features of the city; and Andrew Lang's Oxford: History and Descriptive Notes (1885; new ed. 1890) a charming presentation of Oxford is given both by writer and artist. A manual of the studies of the university is furnished by Wells in his Oxford and Oxford Men (Methuen). A full account of Oxford, civic, ecclesiastical, academic, collegiate, personal, up to the end of 17th century, will be found in the various works of the great Oxford antiquary, Anthony a Wood, in his 'History of the University of Oxford and of the Colleges and Halls,' by J. Gutch (1786-96); his Athenae and Fasti, by Dr Bliss (1813-20; a new edition of these is in preparation); his 'City of Oxford,' and his 'County Seats of England.' From the time of Wood the formal annals of the university become of little interest and very little importance. The interest of books about Oxford rather lies in the diaries which
give the day-to-day Impressions of Oxford residents, Anthony Wood for the 17th century and Thomas Hearne for the 18th (best edition of both by the Oxford University Press), or in the various works of Oxford life in memoirs and autobiographies—e.g. in the autobiographies of Edmund Gibbon, R. L. Edgeworth, &c., and in Stanley’s Life of Arnold. Part of the ground traversed has been generally held from the point of view of modern criticism by James Parker for the city (to the year 1000) in his Early History of Oxford (1838), and by H. C. Maxwell Lyte for the university (1839) in his History of the University of Oxford (1886). See also Reminiscences of Oxford by Oxford Men, edited by Miss Quiller-Couch (1891); S. F. Hulton, Biographical Oxfamian (1892); Joseph Frear, The Police of Oxford (1890-91), and Oxford Men and their Colleges (1893); Wells, Oxford and Oxford Life (1893); Oxford as it is, by a mere Don (1891); Goldwin Smith, Oxford and her Colleges (1895); and The Colleges of Oxford, their History and Traditions, edited by the present writer (1891). Periodical publications are the Post-office Directory and Oxford Almanace; for the university, Oxford University Calendar, Student’s Guide to the University, Biographical Oxfamian, (1891), and the Oxford University Gazette; for the diocese, the Diocesan Calendar and Diocesan Gazette. The local press is vigorous, not to speak of the Oxford University Herald, the Oxford Review, and the Oxford Magazine.

Oxford Clay, the principal member of the Middle Oolite series. See JURASSIC SYSTEM.

Oxford Movement. See ENGLAND (Church of), and KEBLE, NEWMAN, PUSEY.

Oxfordshire, an inland county of England, in southern England, and with an extreme length and breadth of 48 miles by 26; is bounded on the N. by Warwickshire and Northants, E. by Bucks, S. by the river Thames, and W. by Gloucestershire. Area, 755 sq. m., or 483,621 acres. Pop. (1891) 163,149 (1881) 179,559; (1891) 182,598. Flat and bleak in the north and west, except near Edgell (q.v.), on the Warwickshire border, and undulating in the central district, the county in the south presents a succession of richly wooded hills, alternating with picturesque dales, and terminating on the south-east border with a branch of the Chiltern Hills, which, near Nuffield, attain a height of nearly 700 feet above sea-level. Foremost, however, among the natural beauties of Oxfordshire are the numerous rivers by which it is watered, notably the Thames, with its affluents the Windrush, the Evenlode, Cherwell, and Thames. The Oxford and Birmingham Canal affords access to the midland coalfields. The soil in general is fertile, and the state of agriculture advanced, as evidenced by the fact that in 1889, exclusive of 2601 acres under cultivation as orchards and market-gardens, no less than 414,192 acres were under crops, fallow, or grass. Ironstone is extensively worked near Banbury, whilst of manufactures the most important are those of blankets at Witney, paper at Shiplake and Henley, and, to a certain extent, of gloves at Woodstock. The county contains four towns besides the numerous boroughs of Henley, Chipping Norton, Henley-on-Thames, and Woodstock, and parts of those of the city and university of Oxford, and of Abingdon (the remainder being in Berkshire), and 292 civil parishes, all in the diocese of Oxford. Three members are returned to the House of Commons for the county, as also for the city of Oxford and two for the university; the county council numbers seventy-six members. Most of the historical events connected with the county took place at Oxford (q.v.), but apart from them may be mentioned the battles of Clavijo (1649) and Marston, 1644, and the Debates of 1644-46, for which its worthies are Edward the Confessor, Leland (the antiquary), Dr. Heylyn, Viscount Falkland, ‘Doctor’ Fell, Thomas Ellwood, Lord Chief-justice Holt, Rev. James Granger, Warren Hastings, Lord Keeper Guilford, Sir William Beecheys, Miss Edgeworth, Charles Reade, Green (the historian), Lord Penzance, and Vernon Harcourt, and Lord Randolph Churchill. See works by Skelton (1823) and Davenport (1860).

Oxidation is the term applied in chemistry, with a somewhat wild significane, to the changes which occur when elementary or compound substances enter into new combinations with oxygen. The term was introduced in 1777 by Cavendish, to whose chemical notice in which the term Combustion (q.v.) is applied are examples of oxidation. The products of the processes of oxidation are frequently (but not invariably) oxides.

Oxides are compounds of oxygen with other elements, and are amongst the most important of the classes of chemical compounds. Basic oxides and acid oxides are described in the article CHEMISTRY (q.v.). In addition to these two large classes of oxides there are numerous oxides which do not possess either basic or acid properties, or if at all only to a very insignificant degree.

Oxlip. See COWSLIP.

Oxpecker. See BEEF-EATER.

Oxus, the ancient name of a river in western Asia, which is called by Arab writers Jihdn, and by the Asiatists of the regions through which it flows Arab of Jihdn or of Kutha. It rises to the N. of a ridge bounding the Salt-lands between the Tian-Shan Mountains and the Hindukush, and flows west as far as 66° E. long., through Badakshan, and then north-west through Bokhara and Khiva, and empties itself by several mouths into the southern end of the Sea of Aral. There are two main head-streams issuing at 13,042 and 14,177 feet respectively, and uniting in 71° 20' E. long., at 7500 feet. In the first part of its course the volume of the Oxus is increased by numerous affluents, but it receives few tributaries after it turns north-west, its course then running through the deserts of Turkistan. The descent is 90 miles long, and embraces many lakes and marshes. The principal use made of the river is for irrigation purposes; Khiva owes its prosperity entirely to its waters. The river has been ascended for 280 miles by steamboat. It is believed that before the Christian era the Oxus flowed into the Caspian, and that since about 600 B.C. it has twice changed its course. The Russians have been considering the possibility of turning it back again into the Caspian. The physical conditions seem to be favourable, and if the plans now before the legislature of Russia were carried into effect, a navigable highway a couple of hundred miles farther towards the centre of Asia. For the great railway bridge across the river (1888), see BRIDGE, Vol. II. p. 444; and see works by J. Wood (1841; new ed. by Colonel Yule, 1872) and MacGahan (1876).

Oxychlorides, chemical compounds containing both chlorine and oxygen in combination with some other element, and intermediate in composition between the oxides on the one hand and the chlorides on the other. Thus, ammonious oxychloride, SbOCl, is intermediate between ammonious oxide, SbO, and ammonious chloride, SbCl3.

Oxygen (sym. O, atom. wt. 16) is a colourless, inodorous, tasteless gas, long regarded as a ‘permanent’ gas, but liquefied by Pictet of Geneva for the first time in 1877. Its chemical affinities for other elementary substances are very powerful; with most of them it is found in combination, or may be made to enter into combination. The known compounds of oxygen include those formed with several in as many as four different proportions; and there is one only element (thorine) with which it does not enter into any combination.
OXYGEN

Owing to the intensity with which many of these combinations take place, this gas has the power of supporting combustion. It is an eminent degree. It is only slightly soluble in water; 100 cubic inches of that liquid dissolving 4.11 cubic inches of gas at 32°, and only 2.99 inches at 59°. It is slightly heavier than air, its specific gravity being 1.0566.

Oxygen gas is not only respirable, but is essential to the animal life, and hence it was termed vital air by some of the older chemists. A small animal placed in a bell-glass containing pure oxygen will not be suffocated as soon as if it were placed in the same glass filled with atmospheric air. For further details on this, the reader is referred to the article Respiration.

Oxygen is the most abundant and the most widely distributed of all the elements. In its free state (mixed but not combined with nitrogen) it constitutes about a fifth of the bulk, and considerably more than a fifth of the weight, of the atmosphere. In combination with hydrogen, it forms eight-ninths of all the water on the globe; and in combination with silicon, calcium, aluminium, &c., it enters largely into all the solid constituents of the earth's crust; silic—in its various forms of sand, common quartz, flint, &c., limestone, marble, and all the varieties of clay, containing about half their weight of oxygen. It is, moreover, found in the tissues and fluids of all forms of animal and vegetable life, none of which can support existence independently of this element.

The ordinary laboratory method commonly employed in obtaining oxygen on the small scale, the simplest of which consists in the exposure of certain metallic oxides to a high temperature. It was originally obtained by its discoverer, Dr Priestley, from the red oxide of mercury, which, when heated to about 350°, resolves itself into metal mercury and oxygen gas. It may be obtained similarly from red oxide and peroxide of lead, the resulting products being protoxide of lead and oxygen.

The ordinary laboratory method commonly employed in obtaining oxygen on the large scale, but only in recent years has the commercial production of the gas been carried out sufficiently cheaply to enable oxygen to be employed extensively for industrial purposes. The method employed by Brit's Oxygen Company consists in passing air under pressure over barium oxide, BaO, heated to a temperature of dull redness. In this way a quantity of barium peroxide, BaO₃, is formed, and this can be made to again yield its extra oxygen in the pure state (being reduced again to BaO) by heating to a full red heat in a crucible placed with about a fourth of its weight of black oxide of copper, or of binoxide of manganese, the evolution of the gas is greatly facilitated, although the oxides do not seem to undergo any change during the process.

Various processes have been proposed for obtaining oxygen on the large scale, but only in recent years has the commercial production of the gas been carried out sufficiently cheaply to enable oxygen to be employed extensively for industrial purposes. The method employed by Brit's Oxygen Company consists in passing air under pressure over barium oxide, BaO, heated to a temperature of dull redness. In this way a quantity of barium peroxide, BaO₃, is formed, and this can be made to again yield its extra oxygen in the pure state (being reduced again to BaO) by heating to a full red heat in a crucible placed with about a fourth of its weight of black oxide of copper, or of binoxide of manganese, the evolution of the gas is greatly facilitated, although the oxides do not seem to undergo any change during the process.

Oxidation and Terminator (Fr. ourir, 'to hear'; terminator, 'to determine'). See Assize.

Oyster (Ostrea), a genus of bivalves, the members of which are well known to be very passive and very palatable. Structure.—The fundamental characteristics, as displayed by the favourite European species, Ostrea edulis, are those of other bivalves: the shell (culusea) forms a fixed, fringed, or nearly sessile, less sedentary forms move, is almost completely degenerate, the two valves of the shell are unequal, the hinge which unites them is without teeth, and

Swedish chemist having, however, nearly completed his discovery in 1772. Priestly called it Dephylogisti- cated Air; Scheele termed it Empyreal Air; Con- dorct shortly afterwards suggested Vital Air, as its most appropriate designation; and in 1789 Lavoisier, who, by a series of carefully conducted and very ingenious experiments, proved that the combustion of bodies in the air consisted essentially in their combining with oxygen, and thus overthrew the Phlogiston (q.v.) theory, gave it the name which it now retains (from oyx, 'acid,' and general, 'I produce'), in consequence of his (erroneously) believing that it was a neces- sary constituent of every acid.

Oxhydrogen. See Lime-light.

Diagram of Internal Structure.

The dorsal surface is downwards, the anterior or head end to the left. a, region where water enters and leaves the animal; b, the dark line which runs away from the eye to the testa, or where one is placed to expose the other structures; b, gills; c, margin of one of the mantle-folds; d, anterior part of hinge; e, hood over mouth; f, position of mouth; g, b, labial palps; h, end of intestine; i, the closing muscle of the shell; j, position of the heart.

The powerful closing muscle is almost median in position. The left valve of the shell, that by which the animal fixes itself, is hollowed out, while the other is almost flat, and the whole animal is slightly asymmetrical. On an opened oyster it is easy to detect the fringed mantle which lines and makes the shell, the ciliated gills or 'beard,' two somewhat similar flaps (labial palps) on each side of the mouth, which, when a sold, lies near one end of the hinge, the brownish digestive gland, the heart and the kidneys close beside the shell-shutt- ting muscle. 'I suppose,' says Professor Huxley, 'that when the animal feeds in its usual manner'—which is and is gone like a flash of gustatory summer lightning—'glicks along the palate, few people imagine that they are swallowing a piece of machinery (and going machinery too) greatly more complicated than a watch'—in fact a living organ- ism of a high order.

General Life.—The oyster feeds on microscopic organisms which are washed into the gaping shell and on to the mouth by the ciliary activity of the gills and palps; and it may be noted that the greenish tinge, regarded by epicures as one of the highest credentials of an oyster, is probably due to a copious diet of minute green algae. As every one knows, oysters live groggersiously in 'beds' or
‘banks’ at depths of 3 to 20 fathoms, and are strangely fastidious as to locality. They have more enemies besides the dredger, such as the little sponges (Clionid), which bore in the shells; marine worms, and sea-snails (e.g. Purpura and Murex), which also effect an entrance; besides starfishes, which swallow little ones intact, or, embracing larger specimens, insert their arms when the shells are open. Although these passive, they have no eyes or ears they can detect the shadow of an approaching boat; the mantle-fringe and some other parts are undoubtedly sensitive; and some enthusiasts have even inferred ‘intelligence’ from the fact that in the ‘oyster-schools’ and elsewhere the two sexes can be distinguished when the tide retires or when they are transported by rail.

Life-history—There are many interesting facts connected with the life-history of the oyster. Thus, *O. edulis* is hermaphrodite, being first an egg-laying female, afterwards a sperm-producing male, while *O. angustata* and the American *O. virginica* have the sexes separate. Maturity is sometimes rapidly attained, but usually not until the third or fourth year of life, and the maximum fertility is between the fourth and seventh year. The reproductive season generally begins in May, and continues till the beginning of autumn; but its limits are extended or lessened by the conditions of temperature. When the oyster becomes ‘sick,’ ‘milky,’ or ‘out of season,’ the mantle-cavity and the inter-space between the gills are packed with developing eggs, which fishermen call ‘white,’ and at a later stage the eggs are spat. Buckland likened this black spat to fine slate-pennus dust, and the emergence of the young from the mother to a puff of smoke from a railway-engine. He computed the number of developing eggs in an oyster at from 276,000 to 829,000; and Professor Möbius, the greatest German mathematician, calculates that 1000 full-grown parents produce 440 million embryos annually.

These embryos are only about 1/10th of an inch in length, and about two million of them might be packed into a celled inch, but the numbers that rise from an oyster-bank are so immense that the water seems to be clouded. They are very unlike the adults in habit, for they swim actively for some days by means of a protrusible ciliated cushion, or velum. The valves of the shell are transparent, and the young gills, palp, and some of the adult structures have yet to be developed. In the American oyster, the eggs are set adrift at an early stage, fertilisation and the whole of development taking place outside the shelter of the parent. In either case the mortality is enormous; multitudes are washed away to unsuitable localities, and multitudes are devoured by hungry animals; in fact Möbius computes that out of 440 million embryos only 421 individuals reach maturity.

Those that survive become weighted by their growing shells, draw in their ciliated velum for the last time, and sink to the bottom of the sea. They settle on stones, shells, or other ‘culex,’ and often nowadays on chalked tiles or on floating collectors which are placed for the purpose of receiving them. Moored by their left shells, they grow rapidly, from 1/4 of an inch when first attached to a kind of slip or spat, are about two inches, and are known as ‘brood.’ The diameter of an oyster at two years is about two inches, another inch is added in the third year, after which the growth is much less rapid.

*Oyster Kinés.—Oysters are represented by several widely distributed species—e.g. the European *O. edulis* and *O. angulata*, the American *O. virginica* with several varieties, two others from the western coasts (*O. conchaphila* and *O. lurida*)—all of them edible, while the Cape of Good Hope, Australia, Japan, &c. are not without their showy varieties. The size of the shell varies from 3 to 6 inches, but Sir J. E. Tennent found one in Ceylon measuring a little over 11 inches in length. American oysters are often very large. The banks of oysters sometimes form important marine and shore deposits, with the banks of the narrow ‘racoon’ oysters off the coast of Georgia and other parts of North America, which are said to form natural breakwaters. The race is an ancient one, for oysters appear in the Carboniferous strata, and two related forms—Gryphaea and Exogyra—on both heavy shells, are common fossils. The name is sometimes extended to other bivalves, such as the false oyster Anomia (one valve of which is perforated by a tag of attaching byssus), the pearl-oyster Melangrana (see *Pearl*), and the thorny oyster Spondylus.

*Exhibit.?—The accumulations of oyster-shells in the ‘kitchen-middens’ of Neo-Lithic ages show that the appreciation of oysters is no modern taste. To Roman palates the oyster was precious, and the praises of its appetising flavour (prata ingluvies) were often sounded. Those of Linuph (Richborough, Kent) were considered so monstrous that the curiosities and honour of the animal should be as much like an egg-cap as possible. Lastly, the flesh itself should be white and firm, and nut-like in taste. It is by taking the average proportion of meat to shell that oysters should be critically judged. The oysters at the head of the list are of course ‘natives’ (oysters artificially reared); the proportion of a well-fed native is one-fourth meat.

*Oyster and Disease.—Many cases of enteric illness and death having been of late referred to the eating of oysters, some of the authorities on oysters have made searching inquiry into the conditions of oyster culture and storage along the coasts of England and Wales, and carried on bacteriological investigations as to the power of the oyster to absorb, retain, and transmit the typhoid bacillus and the cholera vibrio. It appears from a report in 1894-95 that oysters contaminated by sewage, &c. can do transmit disease; and that in many localities the conditions of culture and storage do expose oysters to the serious risk of such contamination.

*Demonstrations—Some years ago 500 million were sold annually in London, at a cost of £100,000, but the supply has decreased, and the price increased. The total British expenditure in oysters has since been calculated at £2,000,000, for about 240 million oysters. In Paris the annual consumption is said to be 1 million, and the quantity sold in 1892 was 1,654,350 francs in 1853, and 4,500,000 in 1890. In the United States the business employs 60,000 persons and 5000 vessels; some 25 million bushels are sold for $15,500,000. In New York State alone the capital invested now exceeds $1,000,000. The markets are at New York, and other principal markets in car-loads to the west—Milwaukee, Chicago, St Louis, and even San Francisco. The great beds occur in Long Island Sound and Chesapeake Bay;
the former is in part surveyed and divided into plots, not to exceed 500 acres for any one person, for oyster-culture. Art. 4. Ause is found, however, from the Gulf of St. Lawrence to and along the north shore of the Gulf of Mexico, and, though smaller, on points on the west coast, as Puget Sound and Juan de Fuca Strait. In some parts of the United States the Glam (q.v.) rivals the oyster in popularity, particularly in Louisiana.

Supply.—The British supply is derived from three sources—the national oyster-banks, which are gradually getting the attention which they deserve; from the continental banks and farms, especially those of France and Spain; and from the United States, with which a trade amounting to about half a million dollars annually has rapidly grown. Moreover, it must be noted that young oysters are largely imported from France and elsewhere to be "fattened" on British culture-grounds. The practical problem is to keep up a supply sufficient to meet the large demand. For various reasons this seems to be difficult. As oysters live in 3 to 20 fathoms of water, they can hardly be gathered with much selection; they are sometimes lifted by "rakes" and tongs, but usually by the dredge; this is especially true of the English oysters, where, as it secures. There seems some evidence to show that shrew over-dredging has almost ruined some of the banks, but this probably has been exaggerated. Changes in the sea-bottom and in the food-supply have doubtless had more to do with the disappearances. Britain has an innumerable number of banks that are abandoned. Those who permit all kinds of debris and foulness to be emptied into the sea can hardly expect a flourishing oyster-bank in the neighbourhood. To preserve the beds, to observe "close time," to re-stock when the supplies wane, and to prevent pollution are, therefore, effective; but regulations which are satisfactory on paper are often very unsatisfactorily realised. The reader should consult the Parliamentary Reports on British Oyster Fisheries (1870), and on the increasing prices of 1879.

Oyster-culture.—Another practical endeavour which has been richly rewarded is that of artificial oyster-culture. This is of course no novelty, having been practised by the Romans. Thus, Pliny says that "the first person who formed artificial oyster-beds was Sergius Merata (in the time of Augustus), who established them at Baiae... not for the gratification of gluttony, but for the sake of gain, as he contrived to make a large income by the exercise of his ingenuity." In the days of the latter emperors there were well-established Ostreae, and Lake Fusauro, the Achiron of Virgil, a muddy saltwater pond, nowhere more than six feet in depth, has been for many centuries utilised for this purpose. Of oyster-culture there are many different kinds; it may be confined to "fattening" oysters in some conveniently constructed pond or "fallen spit," collected on tiles or artificial "culled," may be brought to the sheltered culture-grounds, where the young can grow in safety; or again, oysters may be bred in confinement, as Professor J. A. Ryder has succeeded in doing in America. In this last case the pond is separate from the sea by a sandbank, through which water alone can and went with the tide; they produced eggs, these grew into "spat," the young fell on suitable collectors, which were afterwards removed to the natural beds. It has even been found possible to fertilise the eggs artificially with sperm from male oysters, and though this is not so feasible in the case of the European species, whose eggs are retained within the parent until they have to some extent developed, there is no theoretical obstacle against breeding them in confinement. Another possibility is to collect the free larvae, which are sometimes very abundant, and transfer them to culture-grounds where the risks of mortality would be lessened. To the success thus attained various forms of oyster-culture, of which details will be found in the reports cited below, certainly warrants further extension and experiment, especially as many authorities believe that there is more hope in this than in any legislative measures to preserve the natural banks. Arcachon (q.v.) and Cancale are important French seats of oyster-culture; in England Whitstable is most notable. The frost of the winter of 1890-91 was estimated to have done £15,000 of damage to the oysters of two companies at Whitstable.

See Parliamentary Reports on Oyster Fisheries (1870, 1876, 1878); Report of the United States Fisheries Commission, viil, which contains not only the results of American observations and experiments but translations of valuable memoirs by Hocke, Hubrecht, and Mohus; Report of Scotch Fisheries Board (J. H. Fullarton on Oyster-culture in France, etc.), 1889; Mohus, Die Austern und die Austernwirtschaft (1877); E. Ingersoll, The Oyster Industries of the United States (1881); W. K. Brooks, Development and Protection of the Oyster in Maryland (1884), and Studies from Biol. Lab. (vol. i. 1888); Huxley, in English Nat. Mag. (vol. i. 1883); and other reports and works of the kind. Oysters and all about them (2 vols. 1892).

**Oyster-catcher** (Hematopus ostralegus), a genus of birds of the family Charadridae, closely allied to the Plovers, and distinguished chiefly by the long, strong, straight, wige-like shaped bill, legs of moderate length, feet with only three toes, all directed forwards and united at their base by a small membrane. The genus, which is cosmopolitan in its distribution, embraces nine species. The only European species, *H. ostralegus*, known also as the Sea-pie and Mussel-picker, is found on many parts of the English coast, and is common in Scotland along the whole east coast, on the adjacent islands even as far as St Kilda, and also on the Irish coasts. Although a coast bird, it often wanders inland, and may be found breeding near inland lochs and on the banks of large rivers. It occurs in Greenland, is common in Iceland, and in many parts of Europe, Asia, and Africa. Its southern migrations extend to Burma, Ceylon, Persia, Mozambique, and Senegal. The adult bird is about 16 inches long, has black and white plumage, orange-yellow bill, erinose irides, and flesh-coloured legs and toes. It is very regular in its feeding habits, passing with great punctuality to feed from the mussel beds. It is gregarious, where it rears itself with mussels, whelks, limpets, anemoids, crabs and small fish. Its eggs, usually three or four in number, are laid on shingle, more rarely among sandflats or even in fields inland, and sometimes on the top of a fairly lofty stack. The oyster-catcher swims well, and takes to the
water of its own accord. Its flesh, though dark in colour, is palatable. H. <i>capensis</i> is a black species ranging from the Cape to the Canaries. Three or four species are confined to America.

**Oystercatcher.** See SALTRAY.

**Ozarka** (Gr. ozo, 'a stomach') is generally used of all diseased conditions of the nose accompanied by great fetor of the breath. This may arise from the ulcers occurring in tubercular or syphilitic disease, or in lupus; from malignant disease; from necrosed bone; or from the presence of a foreign body. But it also occurs where none of these causes is present; and to this form of disease the term is limited by some recent writers (Frankeln, Morell Mackenzie, and others). In these cases there is a peculiar form of inflammation of the mucous membrane of the nose, called <i>dry catarrh</i>, in which the morbid secretion accumulates in the form of crusts in the nasal cavity. This may occasion comparatively little inconvenience, till it leads, as it often does, to the occurrence of an offensive and characteristic odour, the precise cause of which has not been ascertained. It is a very chronic form of disease, for which much trouble is obtained by the frequent use of alkaline and antiseptic washes or sprays. An arrangement devised by Gottstein renders the secretion moist, and so keeps the fetor in abeyance—the introduction of a plug of cotton-wool, which is worn in each nostril for a few hours daily.

**Ozanne.** Antoine Frédéric, was born at Milan, April 23, 1813, studied at Lyons and Paris, and was appointed in 1841 to fill the chair of Foreign Literature at the Sorbonne. He died at Marseilles, September 8, 1853. Ozanne possessed learning and industry, but fate did not favour him in his dream of rivalling the work of Gibbon, save in such fragments as <i>Dans la Philosophie Catholique au XIXe Siècle</i> (1839), <i>Histoire de la Civilisation au VIIe Siècle</i> (1845; Eng. trans. 1868), and <i>Études Germaniques</i> (1847—49). A collected edition of his writings fills 11 vols. (1862—73).

There are Lives by Karker (Paderborn, 1867); O'Meara (Edin. 1876), and Hardy (Mainz, 1878).

**Ozookerite.** See BITUMEN.

**Ozone (Gr. ozo, 'I smell').** It was remarked long ago that a peculiar odour was produced by the working of an electrical machine. Van Marum found that, when electric sparks were passed through a tube containing oxygen, the gas became permeated with this odour—which he therefore called the 'smell of electricity.' Subsequent writers attributed the phenomenon to the formation of nitric acid, due to a trace of nitrogen mixed with the oxygen; especially as the gas was found to act energetically upon mercury. Thus supposed to be explained, those curious results were soon forgotten. But in 1840 Schönbein (q.v.) with remarkable acuteness made a closer investigation of the question, and arrived at many most curious results, all of which have not even yet been satisfactorily accounted for. The problem remaining of great perplexing, as well as interesting, questions imperfectly resolved in chemistry. The earlier results of Schönbein were these: (1) When water is decomposed by the voltaic current, the electrodes being of gold or platinum, the oxygen (which appears at the positive pole) possesses in a high degree the smell and the oxidisable power developed by Van Marum by means of friction-electricity. (2) When the positive electrode is formed of an oxidisable metal these results are not observed, but the electrode is rapidly oxidised. (3) The oxygen collected at a platinum electrode retains these properties for an indefinite period if kept in a vessel; but loses them by heating, by the contact of an oxidisable substance, and even by contact with such bodies as charcoal and oxide of manganese. To the substance, whatever it may be, which possesses such powerful chemical affinities, Schönbein gave the name ozone, from its smell. In 1848 he showed that the same substance can be produced by the action of phosphorus on moist air, and hinted that it might be a higher oxide of hydrogen.

De la Rive and Marignac shortly afterwards, repeating the experiments of Van Marum, showed that electric sparks produce ozone even in pure and dry oxygen, and came to the conclusion that ozone is oxygen in an allotrope state, as diamond is a form of coke or charcoal. Bannet, in 1853, endeavoured to show that there are two kinds of ozone—one formed from pure oxygen by electric sparks, which he allowed to be allotropic oxygen; and the other formed in the voltaic decomposition of water, which he endeavoured to prove to be a tetroxide of hydrogen. Andrews, in 1856, refuted this view, by showing that no such oxide of hydrogen (at least in a gaseous form) is produced in the electrolysis of water; and that ozone from whatever source obtained, is the same body, and is not a compound, but an allotrope of oxygen.

In 1860 Andrews and Tait published the results of a series of volumetric experiments on this subject, which led to some remarkable conclusions—among which are the following:—When the electric discharge is passed through pure oxygen it contracts, hence ozone must be denser than oxygen. A much greater amount of contraction, and a correspondingly greater quantity of ozone, are produced by a silent discharge of electricity between fine points than by a brilliant series of sparks. The contraction due to the formation of the ozone is entirely removed by the destruction of the ozone by heat; and this process can be repeated indefinitely on the same portion of oxygen.

Soret subsequently determined the density of ozone in the liquid state, and showed that ozone absorbs the ozone from the oxygen with which it was mixed by means of oil of turpentine or oil of cinnamon, and observing the contraction produced; and later by determining the relative rates of diffusion of chlorine and ozone. He ascertained that its density is one and a half times that of oxygen. Andrews showed later that ozone is rapidly destroyed when shaken up with dry fragments of glass, &c. He also proved that the effect which is (almost invariably, and sometimes in fine weather powerfully) produced by the air on what are called ozone-test papers—papers steeped in iodine of potassium which are rendered brown by the liberation of iodine—is really due to ozone. He did so by showing that it acts upon mercury as ozone does, and that it is destroyed by heat at the same temperature.

The quantity of ozone in the atmosphere is never great, and it varies within wide limits. Little or nothing is known as to its function in the air, but it is believed to be active in destroying unwholesome substances, owing to its intensely oxidising properties. Ozone has been liquefied by the application of a strong electric current, but no permanent communication between it and water has yet been obtained. It is stated to be blue in the liquid state, and to be liable to decomposition into oxygen, with explosive violence, on sudden diminution of pressure.
P is the sixteenth letter in our alphabet. The symbol was derived from the hieroglyphic picture of a slitter (see Alphabet). When taken over by the Semites, the sign was called $p$, 'the mouth,' a name explained by the fact that in the Egyptian hieroglyph, from which the Phoenician sign was obtained, there are strokes resembling teeth, which, however, disappeared before the date of the earliest extant Phoenician inscriptions. The oldest Greek form was $f$, which differs little from the Phoenician letter. In the Latin alphabet the hook gradually became a loop, giving the form of $F$, and this being the old form of $R$, the letter acquired a tail to distinguish it. In the later Greek alphabet $P$ continued to be the sign for $r$, and the sign for $p$ was differentiated by lengthening the hook, giving ultimately the form $Pi$ for the letter $pi$.

The sound of $p$ is the sharp labial mute. Hence it interchanges with other labials, especially with $b$, the flat labial mute. Most languages give a preference to one of these two sounds. Thus, the Etruscans preferred $p$, and have no $b$ in their alphabet, whereas the Teutonic languages dislike $p$, especially as an initial. Only six primitive Teutonic words, all probably loan words, begin with $p$, and in Beowulf and Cædman, taken together, only three such words are found. In Meso-Gothic the Greek $p$ was nasalized into $U$, but only for foreign words, such as PauL, Pontius Pilate, prophet, and presbyter. Most of our English words beginning with $p$, such as plough, parish, people, or prince, are loan words from Greek, Latin, or Celtic. A primitive Aryan $y$ corresponds to a Teutonic $i$, and it is only a primitive $i$, a very rare letter, which can correspond to a Teutonic $p$. A Welsh $p$ corresponds to a Gaelic $c$ and an English $f$. Thus, the Gaelic mac, 'son,' is the Welsh map or ap. The Gaelic ctithe, the Welsh pedwar, and the English four; and the Gaelic coid is the Welsh pyn, and the English five. Owing to French influence the English prejudice against $p$ begins to disappear in the 13th century, and we get gossip instead of the older godish, apricot for apricott, and purse for borse, though even here the $b$ is retained in the derived verb to disdain. A $p$ also intrudes between $m$ and $t$, as in empty for the Old English emtig, and in tempt in the Old French teinter. In Latin $p$ intrudes also between $m$ and $t$, as in the words exemplum and templem. In like case, as in humble from humilitis, $b$ is usually the intrusive letter in English words.

Paarl, capital of a district in Cape Colony, 40 miles by road N.E. of Capetown; pop. (1891) 7668.

Pabna, a town of Bengal, on an arm of the Ganges, 115 miles N. of Calcutta. Pop. 15,267.

Paca (Colygenys paca). A remarkable genus of rodents, allied to the Agoutis (Dasyprocta), represented by a single species (C. paca), which ranges in Central and South America from Guatemala to Paraguay, east of the Andes. Its cheek-bones are uniquely developed, the zygo-

matic arch being enlarged to form a great cavity on each side. Each communicates by a narrow aperture with the mouth, is lined by mucous membrane, and does not contain food as an ordinary cheek-pouch naturally does. Their function, if they have any, is unknown. The paca is large for a rodent, being about 2 feet in length. It is stout and somewhat pig-like in build, with a large blunt head.

Paca (Colygenys paca).

Pachmarhi, a sanitarium and convalescent depot for European troops in India, is situated, 2500 feet above the plains, in the Central Provinces, 110 miles SW. of Jabalpur.

Pachycephalosaurus, an Egyptian monk of the 4th century, the first to substitute for the free asceticism of the solitary recluse a regular cenobitic system. He was born about 292, and about 340 founded the first monastic institution at Tabenna, an island in the Nile, where ere long there were as many as 1400 monks. He also established the first convent for nuns, which was under the presidency of his sister, and he laboured with so much diligence and zeal that at his death, according to Palladins, not fewer than 7000 monks and nuns were under his inspection. The writings ascribed to Pachomius are not only worthless in themselves, but of dubious authenticity. See the article MONACHISM.
Pachydermata

Gr. 'thick-skinned'), a term applied by Cuvier to hooded mammals (Ungulates) which are not ruminants—e.g. elephants, hyraxes, hog, hippopotamus, tapir, rhinoceros, horse, &c.—and which, with skins of many good reasons the term is no longer much used. See MAMMALS.

Pacific Ocean.—Position and Extent.—The Pacific Ocean is the largest of the great divisions of the ocean, occupying as it does about one-half of the water-surface of the globe and more than one-third of the entire world area. It is almost landlocked towards the north, communicating with the Arctic Ocean by the narrow and shallow Behring Strait, only about 40 miles in width, whereas towards the south it opens widely into the great open southern and Antarctic Oceans. Looking upon its southern boundary as the Antarctic Circle, its length from north to south is about 9000 miles, while its greatest breadth at the equator is over 10,000 miles. Its area is approximately nearly 76,000,000 sq. m.

The Pacific was visited by Europeans in 1518, when a Spanish, Balboa, with a few followers, viewed its waters from the summit of a mountain in Panama; Columbus was aware of its existence, but did not live to see it. The first European to sail upon it was Magellan, who in 1520 entered it after threading his way through the strait bearing his name, and he gave it the designation 'Pacific,' by which it is known to the present day. From about this time was established between Europe and the Pacific countries round Cape Horn. Sir Francis Drake was the first Englishman to sail upon it, entering it in 1577, and afterwards sailing across it as far as the Moluccas. The explorers of the 17th century discovered Australia, New Zealand, and other islands, and during the 18th century the work of exploration was carried on by numerous voyagers whose names are famous in the annals of geographical discovery. Many of them attempted to find passages between the Atlantic and Pacific through the Arctic Ocean; but the problem remained unsolved until MacBride in 1850 discovered the North-west Passage, and Nares in 1853 explored the North-east Passage in the Arctic Ocean, both of which routes are, however, of no practical utility. During the 19th century many exploring and surveying expeditions have completely investigated the region of the Pacific, and among the more recent scientific expeditions special mention may be made of that of H. H. Russell.

River-systems.—Compared with the enormous expanse of the Pacific the area of land draining into it is comparatively insignificant—7,500,000 sq. m., being less than half of that draining into the Atlantic. By far the greater proportion of the land of North and South America drains into the Atlantic, the Andes and Rocky Mountains, which form the watershed, running north and south in more or less close proximity to the Pacific coast. The largest American river is the Yukon in the extreme north, which flows 2000 miles in length, and flows into Behring Sea. Proceeding south, we find the Fraser (900 miles long), the Columbia or Oregon (1750), the Sacramento (420), and the Colorado (1100). The South American rivers draining into the Pacific are little more than mountain-streams. The largest Asiatic river flowing into the Pacific include some of the largest lakes of the world. There is the Amur, 3000 miles in length, flowing into the sea of Okhotsk, and with its tributaries draining an area of nearly 900,000 sq. m.; the Hoang-ho, over 3000 miles long, and the Yen-si-kiang, 3200 miles in length, falling into the Yellow Sea, the combined drainage area of which two rivers is estimated to exceed 1,250,000 sq. m.; whilst flowing into the China Sea there are the Choo-kiang, the Mekhong, and the Menam. The rivers of Australia draining into the Pacific are of slight importance and small size. The total amount of water flowing into the Pacific is estimated at about 5000 cubic miles; the annual river discharge at a little over a fifth of that amount.

Coasts and Seas.—Generally speaking, the American and Australian coasts bordering the Pacific are mountainous and free from basins, while the Asiatic coasts are low and fertile, with many gulfs and bays, and fringed with island groups enclosing numerous seas. The Alaskan shores of North America are low and swampy, while the coast farther south is rocky and rugged, with numerous inlets and small islands, and fringed with islands. The coasts of Japan and China are rugged, with many gulfs and bays. The Indus, Ganges, Burman, and many other rivers flow into the Indian Ocean, and this is fringed with islands; it includes the two extensive Gulfs of Tonquin and Siam. The islands of the East Indian Archipelago cut up this part of the Pacific into several more or less distinct seas, known as the Sulun, Celebes, Java, Banda, and Arfura Seas, the last named coast between the north coast of Australia and New Guinea, and including the Gulf of Carpentaria. The Coral Sea is enclosed by the north-east coast of Australia, New Guinea, New Britain, the Solomon Islands, the New Hebrides, and New Caledonia, and communicates with the Arfura Sea by Torres Strait. The Pacific coast of Australia is mountainous and free from any considerable inlets, the most important harbours being Moreton Bay and Port Jackson, the latter one of the finest in the world. Bass Strait separates the island of Tasmania from Australia. The main islands of New Zealand are separated by Cook Strait, and the principal bays are the Gulf of Haunaki, Bay of Plenty, Hawke Bay, and Pegasus Bay.

Islands.—The Pacific Ocean is remarkable for the innumerable small islands and island groups which it contains. The number of islands by the truly oceanic islands is very small; they are principally congregated towards the central and western portions of its basin, the eastern portion, for some considerable distance off the American coasts, being comparatively free from islands. The principal continental islands are enumerated: commencing at the southern point of
South America, and proceeding northwards along the American coast, then southwards along the Asiatic coast, we have Tierra del Fuego and the islands off the coast of Chili; Vancouver, Queen Charlotte, and the western islands of the coast of British North America; Kodiak Island, off the Alaskan coast; the Aleutian chain of islands, stretching from the Alaskan peninsula towards the Asiatic coast and enclosing Behring Sea; the Kurile Islands, stretching from the Pacific to the Bering Sea, with the islands of the Saghalien; the islands of Japan; Formose and Hainan, off the Chinese coast; the Philippine Islands; Borneo, Celebes, Sumatra, Java, and other islands of the East Indian Archipelago; New Guinea; New Caledonia; Australia and Tasmania; and New Zealand. The oceanic islands of the Pacific are all either of volcanic or coral origin, the volcanic islands lying within the zone of coral-reef builders being fringed with coral-reefs, while there are large numbers of islands entirely of coral formation—coral atolls. The principal groups are the Hawaiian Islands, in the centre of the North Pacific basin, 18° to 22° N. lat., consisting of eight larger and four smaller islands, containing many active and extinct volcanoes, including the well-known Kilauea in Hawaii, said to be the largest active crater in the world; the Bonin Islands, south-east of Japan; the Ladrone or Marianas Islands, between 13° and 20° N. lat., containing several active volcanoes; the Caroline Islands, south of the Ladrones, mostly of coral formation; the Marshall Islands, east of the Carolines, entirely of coral formation; the Gilbert Islands, on the equator, of coral formation and densely populated; in the South Pacific there are the Solomon Islands, the New Hebrides, the Fiji Islands, the Friendly Islands, the Samoa or Navigator Islands, the Society Islands, all fringed by coral-reefs, and the Tuamotu and the Gambier groups of coral islands lying between 10° and 23° S. lat., besides the volcanic Galapagos group on the equator about 600 miles off the coast of Ecuador, and others of less extent and importance.

Depth.—The Pacific was formerly looked upon as remarkably shallow, but we now know that some of the greatest depths in the world occur in it, and that on the whole it is deeper than the Atlantic, its mean depth being about 2500 fathoms. The eastern basin is comparatively uniform in depth, between 2000 and 3000 fathoms, except a large area under 2000 fathoms extending from off the coast of Chili in a westerly direction for over 40° of longitude, while off the north-west coast of North America the 2000 fathom line lies a considerable distance off-shore. The western basin is much more diversified, numerous groups of islands, shallow water, and immense depths occurring irregularly; the greatest depths yet sounded are found in this region of the Pacific. The Challenger's deepest sounding, 4375 fathoms (nearly 54 miles), was in the sea between the Caroline and Ladrone Islands, while the deepest sounding made by a foreign ship, a depth of 4553 fathoms to the north-east of Japan, where a large area of deep water extends off the Kurile Islands and Japanese coast; more recently depths of over 4000 fathoms have been discovered off the coast of Chili, and a British surveying ship has just landed its apparatus on the sea bed of the Fiji Islands, which is the deepest sounding recorded south of the equator. There are many detached patches throughout the Pacific with depths of over 3000 fathoms. The sea bordering on the western basin of the Pacific varies considerably in depth: the depth in the Sea of Okhotsk, the Yellow Sea, and the Java Sea does not apparently exceed 700 fathoms; and the Bering Sea, the Sea of Japan, and the Arafura Sea are all under 1500 fathoms; while the China Sea, Celebes Sea, Sulu Sea, and the Banda Sea are in some places over 2000 fathoms in depth. The bulk of water filling the Pacific is estimated at 170,000,000 cubic miles.

Winds and Currents.—The surface-currents of the Pacific Ocean depend to a great extent upon the direction of the prevailing winds, the principal of which are the two trade-winds, blowing more or less constantly, the one from the north-east, the other from the south-east. By these two regions is what is called the equatorial belt of calms, which is found all the year round north of the equator in the eastern Pacific, but in the west Pacific it is south of the equator during the summer of the southern hemisphere, and during the southern winter it is replaced by a regular southerly breeze; north and south of the trade-winds, also, there are two other belts of calms. In addition to the trade-winds, there are the monsoons, which blow with great regularity, but the direction of which changes according to the season. Monsoons are especially prevalent in the west Pacific, their general direction being south-east, north-east, or north-west, and they cause surface-currents, the direction of which likewise changes with the season. The differences between the temperature and atmospheric pressure over the land and over the water cause monsoon winds. In mid-ocean the winds are found to have a greater velocity than in the vicinity of the land.

The Pacific is practically cut off, as far as the circulation of the deep water is concerned, from communication with the Arctic Ocean by the Bering strait, but towards the south it has uninterrupted communication with the Antarctic. A cold surface-current flows constantly northwards from the Antarctic, dividing into two at Cape Horn, one entering the Atlantic, the other flowing along the coasts of Chili and Peru, thence turning to the westwards; but the cold water frequently met with along the eastern coasts of America is evidently brought from oceanic depths by the action of off-shore winds. The great equatorial current flows to the westward, divided by a counter-current running in a opposite direction in two or three circuits, in the northern one on approaching the Asiatic coast being deflected northwards and finally north-eastwards as the Japan current, which is comparable to the Gulf Stream in the Atlantic; the southern branch is diverted to the southward, flowing along the coasts of Australia and New Zealand, thence curving eastwards, and ultimately merging into the Antarctic surface-current. There are many minor currents, and branches of these more important ones, diverted by the numerous groups of islands.

The broad currents, circling in the one direction in the North Pacific and in the opposite direction in the South Pacific, enclose in their centres two miniature Sargasso Seas somewhat similar to that of the North Atlantic, though not so well marked.

Temperature of the Water.—The temperature of the surface-waters of the Pacific varies with the season, but in the tropical regions the variation is very small. Between the latitudes of 45° N. and 45° S. the temperature of the surface is always above 50° F., while north and south of these latitudes it is more variable. The highest temperature occurs among the islands of the Malay Archipelago and off the Mexican coast, where the mean temperature rises to 85° F., and in the sea between Java and New Guinea the temperature in August reaches 84° F. In the South Pacific the temperature of the surface-water is apparently higher than that of the air, while in the North Pacific the reverse is the case in some places. The temperature of the water below the surface
as a general rule decreases as the depth increases, the lowest temperature occurring at the bottom in great depths, where the bottom temperature appears to be nearly constant all the year round, usually about 33° F. This refers only to the open ocean, for near the mouths of the rivers, the temperature decreases rapidly at first from the surface downwards, and then slowly down to the bottom, irrespective of the temperature difference, which may vary from below 60° to above 80° F.

Salinity.—The salinity of the seawaters of the open ocean varies with the season; increase of evaporation raises, while precipitation in the form of rain lowers, the salinity. In the South Pacific there is a region of high salinity in the neighbourhood of the Society Islands, the maximum salinity being 1.02550 (taking pure water at 4° C. as standard). In the North Pacific the salinity is never so high, the maximum being 1.02050, while in some regions the salinity falls to 1.02485.

For the deposits see the article SEA; see also works cited at CHALLENGER, CORAL, POLYNESIA.

Pacific Railways, a name given to the lines from the eastern side of America to the Pacific coast, which, though not running under one management, yet form a network of lines, constitute with their connections transcontinental lines. (1) The combined Union Pacific from Omaha or Council Bluffs to Ogden, and the Central Pacific, thence to Oakland (for San Francisco), opened in 1869; total distance from Chicago to Los Angeles 2390 miles, time of transit 45 days, fare $90. (2) The South Pacific (1851-83), associated with the Atchison, Topeka, and Santa Fé, which connects Kansas and New Orleans with San Francisco, as well as with Mexico. (3) The Atlantic and Pacific Railway (1882) connecting St Louis with a branch of the South Pacific. (4) The Northern Pacific (1853) from Duluth and St Paul to Portland and to Tacoma on Puget Sound. (5) The Canadian Pacific (1885) to Vancouver. The Panama Railway is also interoceanic, and so will be the trans-Andean line from Valparaiso to Buenos Ayres. (See CHILI, RAILWAYS.)

Packard, Alpheus Spring, an American naturalist, son of the historian of Bowdoin College, was born at Brunswick, Maine, 19th February 1836, graduated at Bowdoin in 1861, and was for a time assistant to Agassiz at Cambridge. He took part in several scientific expeditions, was state entomologist of Massachusetts in 1871-73, and lectured at Bowdoin and elsewhere. In 1878 he became professor of Zoology and Geology at Brown University. But he is best known as a distinguished entomologist; his classification of insects, as proposed in 1863, has been generally accepted. As an evolutionist, Professor Packard is one of the leaders of the Neo-Lamarckian school (see LAMARCK). Besides popular works and textbooks, his writings include Structure of the Oeic- enoptera, of Insects (1865), Anatomy of Limuina Polyphemus (1871-85), The Cave Fauna of North America (1888), The Labrador Coast (1891), monographs on the geometrid moths, the locust's brain, phyllophagous insects, &c.

Packfong, or Petong, a Chinese alloy or white metal, consisting of arsenic and copper.

Paco. See ALFAGA.

Pactolus, the earliest of Roman tragic poets, the sister's son of Ennius, was born at Brindisi about 220 B.C., lived mostly in Rome, and died at Tarentum, ninety years of age (130 B.C.). His dramas, of which only fragments are extant, were found among the Greek models.

Padmin, capital of a residence on the west coast of Sumatra, and seat of the Dutch governor of the west coast province, is situated at the mouth of the Padang River; pop. 15,000.

Paddy. See RICE.

Paderborn, a town of Westphalia, situated 50 miles S.W. of Hanover. The fine Romanesque cathedral (Roman Catholic), completed in 1163, is built over the sources of the Pader (a tributary of the Lippe), which runs across the city of Paderborn. Other noticeable edifices are St Bartholomew's Chapel (1017) and the town-house (1615; restored 1870-76). There are miscellaneous manufactures here; and there are mineral springs close by. The old Hanse town was sacked by the Duke of Lüneburg in 1834 and in the Thirty Years' War. From 1614 to 1819 it was the seat of a Roman Catholic university. Much of it was burnt down in 1875. Pop. 10,941.

Paderewski, Ignace Jan, Polish pianist, was born in Podolia (Russian Poland), 6th November 1860, and began to play as an infant of three. He studied at Warsaw, becoming professor of the piano there in 1878. He was taught in the Strasburg Conservatoire, but thereafter became a virtuoso, making his début at Vienna in 1887, and appearing with phenomenal success at Paris in 1889, at London in 1890, and in America in 1891. He has composed largely for the piano, for the voice, and for piano and orchestra; and is idolised by his admirers of both sexes.

Padiham, a town of Lancashire, 3 miles W. of Burnley and 8 NE. of Blackburn. Cotton is the staple manufacture, with coal-mining and stone-quarrying. Pop. (1891), with Hapton, 11,311.

Padilla, Juan de, one of the most popular heroes in Spanish history, was a seigneur of a Toledo family, and was appointed by the Emperor Charles V. military commandant of Saragossa. While he was so employed a formidable rebellion, caused by the excessive taxes which the emperor imposed on the Spaniards, to defray the cost of his various wars in Italy, Germany, and the Low Countries, broke out among the towns of Castile, and the rebels, who were known as the Calahorra of Padilla, set up Padilla as their leader at their head. He was successful in a number of enterprises undertaken against the royalist party, but on 23d April 1591 was completely beaten at Villalos. This conflict decided the fate of the rebellion and of Padilla himself, who was taken prisoner, and next day executed. His wife, Donna Maria de Pacheco, rallied the remnants of the rebel army, and for a long time held Toledo against the royalist besieging army; after its fall she retired to Portugal, where she died in 1531. Numerous poems and dramas celebrate their deeds.

Padishah, in Turkish PAĐIȘAH (Persian padî, 'protector' or 'throner'), Shah (Persian, 'prince'), one of the titles of the Sultan of the Ottoman empire, and of the Shah of Persia.
Padua (Ital. Padova), a city of North Italy, 23 miles by rail W. by S. of Venice and 18 SE. of Vicenza, is still surrounded with walls. The principal streets are lined with arcades; most of the others, especially in the older parts, are narrow, dark, and ill-paved; but there are several handsome arcades and squares. The collection of public buildings belongs to the municipal palace (1172-1219), a huge structure resting on arcades, with balconies running round the upper story. The roof (1429) of its great hall (267 feet long, by 61 wide, and 78 high) is perhaps the largest in Europe unsupported by columns. The churches (nearly fifty) include the cathedral (1532-1754); St. Anthony (1230-1397), said to have been designed by Niccolò da Pisa, a building in the Pointed style, with Byzantine blendings, and a richly decorated interior by Donatello, Sansovino, and others—the bones of St. Anthony rest in a side-chapel; St. Justina (16th century), a fine Renaissance church, with an altarpiece by Veronese, and other pictures; church of the Eremitani (13th century), with frescoes by Mantegna; the church of the Scaligeri, adorned with the Cappella Giotto; and the church of St. George (1377), with frescoes by Avanzi and Altichieri. The "saint's school" is adorned with frescoes by Titian and his pupils, illustrating the life of St. Anthony. Donatello's fine equestrian statue of Gattamelata, the Venetian soldiery in front of the numerous frescoes at St. Anthony. Padua has enjoyed greatest fame from her university, founded by the emperor Frederick II. in 1221, though the fine Renaissance buildings date from 1493-1532; there are now 80 teachers and 1100 students. To it is attached one of the oldest botanical gardens in Europe, and a library (1029) of 158,500 vols. and 2500 MSS. The city museum (1881) contains antiquarian art, and numismatic collections, a library, and archives. There is not much industry or much commerce, though leather, cloth, and gut-strings are prepared. Pop. with suburbs (1897) 81,300.

Paducah, capital of McCracken county, Kentucky, on the Ohio River, 48 miles above its mouth, and just below the entrance of the Tennessee, 226 miles by rail W.S.W. of Louisville. It has a large trade by river and rail, and contains shipyards, foundries, railway-shops, flour, saw, and planing mills, distilleries, tanneries, soap, vinegar, i.e., furniture, tobacco, &c. Pop. (1880) 8036; (1900) 19,446.

Pam (of doubtful etymology), the name given by the ancient Greeks to a kind of lyric poetry originally connected with the worship of Apollo.

Pădești-baptists. See BAPTISTS.

Păgâna, or Păgony. See PEE.ONY.

Pâgest, an anciently a Greek city of Lucania, in Southern Italy, on the present Gulf of Salerno. It was founded by the Corinthians some time between 650 and 600 B.C., and was originally called Pale- donia. It was subdued by the Lucanians, and from them passed to the Romans, who established a colony there about 273 B.C. The Latin poets sing the praises of its roses, which bloomed twice a year. Pâgest was burned by the Saracens in the 9th century, and ravaged by Robert Guiscard in the 11th, and never recovered from these disasters. Portions of the ancient walls and three well-preserved Doric temples remain. See Labrouste, Les Temples de Pâgest (1877).

Pagnani, Nicolò, the famous violinist, was born a portér's son at Genoa on 18th February 1784. His genius showed itself early, and, practising sometimes a single passage for ten hours running, he acquired a mastery over his instrument that has never been equalled; the violin, indeed, ascribed it to diabolic agency. It must be confessed he was too much addicted to mere feats of musical legerdemain. He gave his first concert as early as 1793; began his professional tours in Italy in 1803; in 1827 received from the pope the order of the Golden Spur; in 1828-29 played a great sensation in the chief towns of Austria and Germany; and in 1831 created an equal Juvro in Paris and London. He had gambled much in youth, but he returned very rich to Italy; and he died at Nice on 27th May 1840, drawing a last long note on his favourite G-string.

See his Life in French by Fàtis (1851), in Italian by Bruni (1873), and in German by Nigg (1882); also vol. ii. of Grove's Dictionary of Music (1880), and Engel's From Mozart to Marie (1890).

Page (derivation variously assigned to Gr. paía, 'a boy,' and Lat. paio of a 'village'),] a youth of noble or good birth employed in the service of a royal or noble personage. The practice of employing youths of noble birth in personal attendance on the sovereign existed in early times among the Persians and Romans, and was a special feature of feudal chivalry in the middle ages. A degree of page was preparatory to the further degrees of esquire and knight. The practice of educating the higher nobility as pages at court began to decline after the 15th century. Pages still figure, however, on ceremonial occasions at the chief courts of Europe; and the page of St. Petersburg is a cadet school for the Russian Guards.

Pâget, Sir George Edward, K.C.B., was born at Yarmouth in 1809, and educated at the Charterhouse and at Cambridge. He took his B.A. degree in 1831, became Fellow of Cains in 1832, D.C.L. in 1836, D.C.L. of Oxford and Durham, LL.D. of Edinburgh, and Fellow of the Royal Society. He was appointed regius professor of Physics in Cambridge, and became K.C.B. in 1883. Sir G. Pâget may well be regarded as a public benefactor, he having taken the principal part in the great advance lately made in the education of medical practitioners. He died in 1892.—His younger brother, Sir James Pâget, Bart., was born at Yarmouth in 1814. He became member of the Royal College of Surgeons in 1836, Hon. Fellow in 1843, member of the Council in 1865, president of the College in 1875, Traiulhye Lecturer in 1886, 1895. Pâget was Surgeon to the Queen, Surgeon to the Prince of Wales, and consulting surgeon to St. Bartholomew's Hospital, he was created baronet in 1851, and in the same year LL.D. of the university of Edinburgh. Two of his earlier works are Lectures on Surgical Pathology (1851) 4th ed.; Lectures (1875). He was vice-chancellor of the university of London, and a member of the Institute of France (Academy of Sciences). Died in 1900.

Pagoda (a Portuguese corruption of the Persian bat-khâdâ, 'nobil-temple') is originally an Indian temple of the approximately pyramidal shape especially characteristic of the Dravidian style (see Vol. VI. p. 109). Thus, the great pagoda at
Tanjore has a perpendicular part two stories in height, 82 feet square, and above that thirteen stories, forming an elongated pyramid about one hundred feet high. The basement section is simple in outlines, but adorned by niches and pilasters; the pyramidal portion is somewhat elaborately sculptured; and the whole is crowned by a dome (said to consist of a single stone), which brings the total height to one of two great courtyards, and in the same court stand several small shrines, one of which is so beautifully carved as to rival in interest the great temple.

The date of the latter is not certainly known, but is with much probability referred to the beginning of the 14th century. The so-called ‘Thousand Pagodas’ of Sriramanthan (q.v.) in Java are obviously modelled on Hindu originals, either Jain or Buddhist. The Burmese pagodas are described and illustrated at Vol. II., p. 565. The term is also loosely applied to the Chinese lao, or tapering tower, of which the most famous was the Porcelain Tower of Nanking, described at Vol. III., p. 186. This was erected in the beginning of the 15th century only nine of the proposed thirteen stories, cased in white porcelain, were completed, and the height never exceeded about 290 feet. It was destroyed by the Taiping in 1856.

First-class pagodas have seven, nine, or thirteen stories, the more numerous second-class ones usually three or five. Pagodas are occasionally still erected—sometimes of iron.

**Pahang.** Or PAKANG, a Malay and Moslem state on the west coast of the Malay Peninsula, since 1887-89 under British protection and connected with the Straits Settlements (q.v.). Pahang has an area of 10,000 sq. miles, and a pop. of 57,462. The capital is Pekan on the Pahang River.

**Pahlanpur.** See PALANPUR.

**Paine, Thomas,** deistical and radical writer, was born at Thetford in Norfolk on 20th January 1737, the son of an ex-Quaker staymaker. He himself had been a staymaker’s apprentice, but at the age of nineteen became a Christian, and in 1772, after a short stay in London with a printer (q.v.), became engaged as an agent for an American shipowner, and was rewarded for his services by the post of Secretary to the Committee of Foreign Affairs. He lost that post in 1779 for divulging state secrets, but was appointed clerk of the Pennsylvania legislature, and in 1786 received from congress $39000 and the confiscated farm of New Rochelle. In 1787 he returned to Paris, to England, where in 1791–92 he published The Rights of Man, the most famous of all the replies to Burke’s Reflections upon the French Revolution. The work, of which a million and a half copies were sold in England alone, involved many in heavy penalties; Thomas Paine, for instance, for circulating it got fourteen years’ transportation. Paine, however, had slipped off to Paris, having been elected by the department of Pas-de-Calais its deputy to the National Convention. Here he voted with the Girondists, and at the trial of Madame du Stael, ‘proposed what would have done France honour—the offer to the king of an asylum in America.’ He thereby offended the Robespierre faction, and in 1794 was thrown into prison; just before his arrest having written part i. of The Age of Reason against Atheism and Christianity, and in favour of Deism. Part ii. appeared in 1796, and a portion of part iii. in 1807. The book alienated Washington and most of his old friends; and it was not till after an imprisonment of eleven months that he was released and restored to his seat in the Convention. He became, however, disgusted with French politics, and occupied himself chiefly with the study of finance, till in 1802 he returned to America in a ship placed at his service by President Jefferson. He died at New York 8th June 1809. The stories about his intemperance were greatly exaggerated. In 1819 his bones were removed by Colbeck (q.v.) from New Rochelle to England; their whereabouts since 1847 is unknown. ‘Paine’s ignorance,’ says Leslie Stephen, ‘was vast and his language brutal; but he had the gift of a true demagogue—the power of effecting a fine vigorous English pamphlet.’

The complete edition of his works is that by Mendam (3 vols. London, 1830); of his numerous biographies may be mentioned those by ‘Francis Oldys’ (i.e. George Chalmers, 1791), Chetham (1809), Rickman (1814), Sherwin (1815), and Vese (1841). See also Leslie Stephen’s History of English Thought in the Eighteenth Century (1880); an article by Moncre D. Conway in the Fortnightly for March 1879; and Alger’s Englishmen in the French Revolution (1889).

**Pains and Penalties.** See ATTAINDER.

**Painted Lady.** See BUTTERFLY, H. 589.
TESAKA PAGODA, KYOTO, JAPAN.
Painting

Painter. William, author of the Palace of Pleasure, was most probably a Kentishman, and born about 1525. He seems to have been master of ceremonies in the household of the Earl of Essex from 1547, and the first volume of The Palace of Pleasure, being an increase of the art of painting, was published in 1594.

The first volume of The Palace of Pleasure was dedicated to the Duke of Buckingham, who had been knighted by the queen at Whitehall on August 23, 1573. It was dedicated to the Duke of Buckingham because he was a great patron of art and literature, and his patronage helped to establish a new movement in English literature and art.

The work was completed and published in 1594, and it was dedicated to the Duke of Buckingham because he was a great patron of art and literature, and his patronage helped to establish a new movement in English literature and art.

Painting

Painting is a form of visual art in which an artist uses paint to create a two-dimensional or three-dimensional work on canvas, paper, or other supports. It is one of the oldest arts, with evidence of painting on walls and pottery dating back to the Neolithic period.

Painting involves the use of paint to create images on a surface, and it can be divided into two main categories: representational painting and abstract painting. Representational painting aims to create a recognizable visual representation of the world, while abstract painting focuses on the use of color, shape, and form to create a composition that is not necessarily related to the physical world.

Painting has been significant throughout history, and it has been used to communicate ideas, emotions, and events. It has been a medium for self-expression, a means of social commentary, and a way to record history.

Painting has been a major art form for centuries, and it continues to be a popular medium today. Artists use paint to create a wide range of works, from portraits and landscapes to abstract compositions and installations.

Painting is a form of visual art in which an artist uses paint to create a two-dimensional or three-dimensional work on canvas, paper, or other supports. It is one of the oldest arts, with evidence of painting on walls and pottery dating back to the Neolithic period.

Painting involves the use of paint to create images on a surface, and it can be divided into two main categories: representational painting and abstract painting. Representational painting aims to create a recognizable visual representation of the world, while abstract painting focuses on the use of color, shape, and form to create a composition that is not necessarily related to the physical world.

Painting has been significant throughout history, and it has been used to communicate ideas, emotions, and events. It has been a medium for self-expression, a means of social commentary, and a way to record history.

Painting has been a major art form for centuries, and it continues to be a popular medium today. Artists use paint to create a wide range of works, from portraits and landscapes to abstract compositions and installations.
even by the most famous men, would appear to us still primitive from the pictorial point of view, though it is certain that the drawing of the figures would be well executed and colored. We have evidence whatever in the classical paintings which have come down to us that the ancients ever mastered the craft of painting in the modern sense—i.e. as an art which interprets truths of effect and which studies not only the forms but the texture and qualities of the material. The great Greek painters must have been fine linear draftsmen, and they would colour their drawings carefully; but all Greek art that is known to us has a clear and positive quality incompatible with the richness, the mystery, and the subtle truth of painting in its most advanced stages. With regard to the colouring of the Greeks, Sir Joshua Reynolds praised them for having used only four colours, and said that four are sufficient to make every combination required. Sir Joshua probably was thinking of the flesh-colour only, which has since been painted by Etty with very few colours. MacIise said of Etty that 'with three colours and white—anything approaching to a yellow, a red, and a blue—he could produce a sweetly-coloured picture.' The Greeks in like manner could not have imagined their pigments to be quite sufficient to imitate the full colouring of the natural world without a complete palette. Apelles himself could not paint a primrose with yellow ochre, nor a geranium with red ochre, nor is there any means of mixing black and white so as to imitate the azure of a southern sky. It is therefore of the greatest interest to ascertain whether the Greeks had a complete palette or not. Here the difficulty is to know at what date each pigment came into use. The vague expression generally employed is that certain colours were known to the ancient writers. Pliny says that Polygnotus and Micon used yellow ochre only. Vitruvius is said to have been 'first prepared by Kallias the Athenian five hundred years before the Christian era,' and minium (red lead) was first used by Nicias, a painter of Athens in the time of Alexander. It is highly probable that the Greeks would be acquainted with Egyptian colours, and the Egyptians knew the madder-root. The Tyrian purple and Egyptian blue were too famous for the Greeks to remain ignorant of them. Yellow and red ochre were also known to the ancients. Black and green was used by Polygnotus and Micon, and ivory black is said to have been employed by Apelles. As for vehicles, there is a well-known passage in Pliny which Sir Joshua Reynolds interpreted as a description of glazing, that is, repainting with transparent colours; but it seems more probable that such accounts have come down to us as really mean no more than varnishing. The use of the word 'atramentum' by Pliny seems to imply that the varnish darkened the picture, which it would do if it were not transparent. It is general modern parlance that the works of the Greek painters were executed in distemper and varnished afterwards, except their encaustic pictures, tidily executed with melted colours. Distemper or tempera (the Italian word for the same thing) is a kind of painting in which the pigments are mixed with glue, so that any kind of thin glue or white or yolk of egg with vinegar. We believe that the Greeks possessed oils and varnishes, but there is no evidence that they ever practised what we call oil-painting.

However, a tempera picture protected by a coat of varnish was well valued by connoisseurs of the same generation. But the ancients seem to have held the application of the various kinds of pigments and enamels to oil-painting only by experts. As to their palette the probability is that the extremely restricted list of pigments which has been attributed to them was a matter of choice rather than of necessity for con-

vventionally under-coloured work, or they may have begun their paintings with very few colours, as Titian did afterwards, and finished them with a fuller palette. We have no important works by famous artists, but there is an ample supply of such ordinary painting as was applied to the decoration of houses and tombs; and from this we may infer at least the technical condition of higher art. The variety of pigments was evidently sufficient to give a full scale of colouring by mixture or superposition and, as oils and varnishes were known, it might have been possible for oil-painting to be used whenever a classical painter desired for it as everything was ready for painting, yet the final step was not taken. The art of tempera or size-painting remained technically much what it had been before, except that there may have been greater freedom in execution and in choice of subject. Classical taste in painting continued with a tradition of old methods for a considerable time after the introduction of Christianity, and even when the nude figure was no longer a subject of study tempera painting was still practised, though more stiffly than in classic times. The Byzantine painters of the masters of Pompeii to medieval work is marked by more than a technical decline. In reading histories of painting we may be on our guard against the careless and inaccurate employment of the word 'fresco.' It really means painting on fresh plaster—i.e. on plaster that is still wet; but the word is inaccurately used for paintings on dry plaster also. The practice of painting on walls covered with plaster is as old as ancient Assyria, and it has been believed that the ancient Greeks understood true fresco, principally on the strength of an expression of Plintarch, 'eu' Augeniouz eu'syndemouz,' to paint on a wall we must dry it. Vitruvius, too, speaks of a wet ground, and, although he does not directly say that it was painted upon when wet, he says that, so prepared, it was fit for pictures, and that colours on it are permanent. This permanence of the colours is the characteristic of true fresco. Unfortunately, Plutarch compares painting on the wet with encaustic as evanescent to permanence.

Whether may be the real antiquity of true fresco, it is certainly a much older process than oil-painting. It was understood and practised in Rome even in the time of Augustus. The painting of churches was already in great request. The process is as follows: On the second coat of ordinary mortar is spread a coat of fine old lime mixed with well-sifted river sand. In a few hours (say from three to six, according to temperature) this begins to dry, and the work of painting must be completed before the drying begins, consequently a small surface of plaster is laid at a time. All honest and conscientious fresco-painters, such as Antonio Veneziano, resisted the temptation to touch on the dry plaster; but the careless or the incompetent cannot resist, though such retouching is simply cheating, as it is really not in fresco, and not permanent.

The technical process of fresco was well understood in Italy whilst art itself was still in a primitive condition. Cimabue, Taddeo Gaddi, and Giotto, and many less known, were all employed in fresco as well as in tempera, so that all the technical part of the craft was a matter of ancient tradition when Raphael and Michelangelo took it up on their own account, and brought it to far greater powers of mind. To appreciate the progress made by these great artists is only to refer to the still and mindless Byzantine art from which that of Cimabue was already a partial emancipation.
Painting

After the invention of oil-painting the inconveniences of fresco were more strongly felt, and many artists turned away from it to the new process. True fresco cannot be retouched; it has to be painted darker than the artist's intention, as it lightens in drying, and it must be painted from small cartoons. The result often is flat, inimitious and has no gloss, and so is suitable for mural decoration. Raphael seems to have liked fresco and oil equally well. Michelangelo greatly preferred fresco, as better suited to his powers. Leonardo da Vinci, with his great mural work, 'The Last Supper,' in oil, though fresco must have naturally suggested itself.

Many modern attempts to revive fresco have been made in Europe. They have rarely been successful, and have especially failed in the Houses of Parliament, where many works have been painted prematurely. Modern failures have led to the adoption of a process on dry plaster, fixed afterwards with water-glass in spray, as in Maclise's large works in the Royal Gallery; but this is not absolutely durable. The best substitute for true fresco is the 'oil fresco,' employed by Sir Frederick Leighton for his large compositions at South Kensington. These are painted with a spirit medium on dry mortar. In France a substitute for fresco has been found in painting on canvas with a dead surface, the canvas being afterwards fastened to the wall with white lead. True fresco may now be considered almost a dead art.

The next step in importance in the history of art is the discovery, or earliest known practice, of what we call 'oil-painting,' which includes the use of varnish. During the progress of the process it has been generally assigned to John Van Eyck, who was born about 1390; but it is now believed that his elder brother Hubert may have an equal if not a better claim. Both certainly worked in the new method, and John continued it after his brother's death. Since then the practice of oil-painting and of varnish-painting has been carried without interruption down to our own time, and, though it has undergone much technical development, it remains essentially distinguished from tempera by the mixing of varnish with the colours themselves and by the consequences in execution to which this mixture has led. The brothers Van Eyck themselves were far from anticipating the future freedom and power of oil-painting. Their work was beautifully executed in oil, but was inflexible and lifeless in execution of small works, it has lasted wonderfully; but their careful rendering of detail belongs to the infancy of art. An Italian student of painting, Antonello da Messina, stayed in Flanders for some time and worked under John Van Eyck. He afterwards returned to Italy by way of Venice, and from him the knowledge of the new method spread to Florence, and thence to the other cities of Italy. The date of Antonello's death, which occurred in Venice, is not precisely known, but appears to have been before 1479.

It may be convenient to remember that the year 1500 saw the practice of oil-painting firmly established in the north and south of Europe. It did not immediately win the absolute pre-eminence that it has subsequently attained. Michelangelo expressed his independence in the matter by his actions rather than by his words, due to the fact that its full powers were not yet developed by his neighbours. The name of Raphael as an artist is due to other qualities than the technical merit of his oil-painting, which remained comparatively primitive. The earliest practice of oil-painting was unimportant, if not inferior, to tempera, the signs of the ground showing through the colors; and, although the early oil-painters manifested a workman-like skill in dealing with their materials, they displayed no power of handling. The manual precision of Albert Dürer has never been surpassed, yet his work as a painter is primitive. Roman painters of the time of Michelangelo might use oil as a convenience, but they could have expressed themselves perfectly in fresco. When we come to the Venetian school the case is very different. There was a harmony between the technical methods of oil and the genius of the Venetians which led to the highest technical excellence. Van Eyck and his followers, both in Flanders and Italy, painted upon a transparent monochrome. Titian used a substantial dead-colouring in which he could make whatever alterations he chose, and afterwards worked upon that by successive glazings till he obtained the utmost richness of quality. The notion that Titian had some secret that died with him may be dismissed as purely fanciful. His method of painting is well known, and the superiority of his imitators may be accounted for by his natural genius and by favourable circumstances. His master, Bellini, drew carefully after nature and this was followed by Titian's primitive, because it is still coloured drawing. Titian's painting the different kinds of technical knowledge are so completely fused together that he is not the draughtsman who colours, but the painter. The same is true of Giorgione, almost equally gifted and surpassed by Titian in the circumstances of his life.

Rubens was a great master of the technique of painting in another way. He painted much in transparent or semi-transparent colours over a first painting in transparent brown monochrome; but, instead of leaving the lights thin that the white ground might show through as in the practice of the early Flemish painters, Rubens loaded his lights with thick opaque colour. His way of painting was technically very systematic, which permitted an execution of rapidity. There is evidence that he followed the early practice of mixing varnish with his colours, at least when transparent and for linear sketching with the brush. The technical execution of Velasquez is a model of excellence in the use of both transparent and opaque colours in the variety of his brush. It is not so methodical as that of Rubens, being always subordinated to the artistic intention of the painter.

The most perfect works on a small scale have hitherto been those of the Dutch painters, Teniers, Terborgh, Metsun (or Matsys), Maes, Rubens and many of the others of the same school. Their method of painting was almost universally to begin with a transparent brown monochrome on which they painted the shadows thinly, giving more substance and opacity to the lights. Being limited in their aims, and painting chiefly what they could see around them and study at their own convenience, they attained a high degree of technical excellence. Their drawing is almost invariably careful and true, and their colouring harmonious, whilst the quality of their pictures is generally admirable.

The practice of modern artists is always founded upon that of one or other of the masters we have mentioned. There are not very many ways of painting, or if they seem to be many they are reducible to a few very simple principles. The early method of giving luminous reflections is now superseded, the white ground show through them is seldom followed in these days, but it has been resorted to occasionally. The practice of Rubens, by which the shadows are painted thinly and the lights more thickly, is more generally followed in modern schools. Reynolds, who painted first a strong, luminous under-ground with few colours and glazed upon it afterwards, worked on the principle of Titian. Landseer's
practise was essentially that of the Flemish school, and St. Peter's (in his best works) that of the Dutch. Turner approached much more nearly to the Venetian practice than to that of Rubens, as he dead-coloured broadly and afterwards painted in detail on the dead-colour, using glazes and scumbles (opaque colour used thinly): but Turner's practice was hardly ever found in French, pleine pâte introduced by Decamps, and often exaggerated by his imitators. The novelty here was, however, rather in the brush-work than in the use of thick pigments themselves. Many French artists have also blurred their outlines in revolt against the cold definition of the classical school, but the originality was rather in the manner of doing it than in the mere softening of the outlines, as Titian, Correggio, Reynolds, and others had already carefully avoided the early hardness of definition.

Although the technical method of oil-painting as a new art and by the absence of gloss, though it cannot replace fresco in mural decoration. Water-colour, as a process, is much more ancient than oil, having been extensively employed in various ways during ancient and medieval times; but the method of using it that gives the process its present intellectual value is essentially modern and English, dating from the early years of the 19th century. The practice of the 18th century led up to it by the use of broad washes in sepia or in neutral tint, afterwards more or less coloured, an adaptation of the Dutch and Flemish practice in oil-painting, except that the finished result stopped very far short of full colour. The water-colour of the present day has discarded the monochrome wash, beginning with pale washes in colour, and working from light to dark. In its perfection modern water-colour is distinguished by exact freshness and brilliancy; it is important not only as an independent art, but by its great influence on modern oil-painting. The majority of oil-painters have themselves employed water-colour as an auxiliary for studies, especially in landscape, and much of the light and air in modern oil-painting may be attributed to its influence. Water-colour, in our own century, has proved a compensation for our failure in the attempted revival of fresco. Though apparently of inferior importance, because practised on a small scale, it has taught what fresco taught and more, as it has educated us in the use of modèle. Improvements in the materials of water-colour have led some of its practitioners to attempt rivalry with the force of oil, which is unnecessary, as oil must ever remain the more powerful medium of the two, and water-colour has its own superiorities in freshness and delicacy. Thero does not seem to be any probability that either of the two arts will ever be replaced by a new discovery as tempera was superseded by oil, nor is it likely that the technical methods will be improved. There is room for improvement in a stricter abstinence from the use of evanescent or destructive colours; but unless very severe precautions are taken to secure the permanence of their works.

Water-colour was despised in France until the fall of the second empire; but the example of English artists has led the French to the study of it, and now many of them pursue it with success. Their work is often admired, but is not always direct, and their influence is almost exclusively in favour of freshness and decision.

(2) The Intellectual History of Painting.—Under the Egyptian dynasties painters were recorders of events and decorators; in Assyria they illuminated a sort of pictorial history of royal deeds. In both these cases there could be very little room for the exercise of individual intellect in the artist, who was seldom more than a manual workman, laying on colour according to methods prescribed for him by authority. Even in Greece we have evidence that the art of picture drawing was a handicraft by the class of gentlemen and scholars; however, Greek painters of eminence attained individual distinction, and such a complete degree of personal emanation that they were free to exercise whatever intellectual power they possessed. There is not much expression in Greek sculpture, but there is some, and what there is proves quite sufficiently that the subtle and acute intellect of Greece could express itself in art as effectually as in literature. What remains to us of Greek and Roman caricature is good evidence of faculties that could doubtless have turned themselves, by an alliance with a higher form of art, in what we now call genre painting. Still, we have no direct proof that the fine arts in Greece ever really were intellectually so great as her poetry, her philosophy, and her drama. In the decline of classical art we find little more than the current production of an inferior class of men for the adornment of habitations or tombs. The beginnings of Christian art, still in design and laboriously ornamental, give hardly any evidence of intellect; the artists who produced that art were in a condition of mental and moral decay, but it came to be eminently a decorative art, with power, beauty, and majesty, but with no intellectual originality or power of personal emanation. The medieval representation of the Virgin in the ivory and enamel of the 10th century, of the Virgin in the ivory of the 13th century, is a complete illustration of the art of painting as applied in the early Middle Ages. The high art of the Renaissance, the art of painting had its full share in the general activity, and assumed a place by the side of literature which it has ever since maintained. Nevertheless, the necessity for high manual accomplishment and technical skill, which were an advantage to the workman over the thinker; and so we find, as in many Dutch pictures, that clever representations of the most commonplace subjects preserve their value though almost destitute of mind. There can be no more striking contrast than that between a Dutchman toiling for six weeks on the representation of a besom and Michelangelo painting a prophet in half a day; yet the Dutchman is immortal too. The intellectual progress of art has been marked by the extension of its influence, and in latter Christianity the art of painting began again from fresh beginnings, without either technical or intellectual preparation. Its first awakening of sympathy is with the human side of Christianity, the love of mother and child, the sufferings of the crucified Christ, the sorrow and bereavement of the disciples. As religious art
advances, its mental progress is shown by the increasing importance given to the human side of its subjects and the diminution of ornament in its dress, till at length the dresses become simple draperies, almost without jewels or embroidery, and the charm of the work lies in the beauty of the subject and the sensitiveness of the artist's attitudes. With the Italian Renaissance the art of painting made a great intellectual advance by its sympathy with what was then the new activity of scholarship. Raphael was, if not himself a scholar, the intimate friend of scholars, working constantly under their influence; being also a wise architect and an archeologist. The selection of 'The School of Athens' as the subject of one of the most important mural pictures in the Vatican is most significant. In Leonardo da Vinci the artistic is united to the scientific intellect; in Rubens it is united to the broadest culture of the scholar and the man of the world. Rembrandt may not have been a learned man, but few authors or artists have shown more sympathy with different classes, or have discerned so well the dignity that may be found in the least or the unlearned, to the rich or the poor. The pictures and etchings of biblical subjects by Rembrandt bring them nearer to us by their homely truth than the ideal conceptions of Raphael. 'Surely we cannot refuse the title 'intellectual' to an art which contains a philosophical compound of all these elements.' The faculties of Teniers and Ostade are narrower and lower, yet even in their works there is a sympathy with the humbler classes which has lasted down to the art of our own day, which was lived in the art of Wilkie, and is graver and more powerful in that of Irenee.

All portrait-painting of any importance has endeavoured not only to copy the features, but to express as much as possible of the mind; and the knowledge we derive from historians and biographers is felt to be incomplete until we have referred to the canvases of some observant contemporary artist, such as Holbein, Van Dyck, Velasquez, Reynolds, or Raeburn. Even in these days of photographic invention the portrait-painter keeps his place, great portraits are painted still, and future students will still look back to his work as an aid to the photograph alone, but will go for the intellectual element to the canvases of Millais or a Bonnat. Closely connected with portraiture is the art which observes and records the passing phases of social life, an art which reached perfection in the 18th century. Nobody could have been so characteristic and true a truthful picture of Hogarth. The representation of contemporary life, in drawing-rooms and elsewhere, has been actively pursued down to our own day in all the leading schools of Europe, and is now practised more than ever, especially in France, where the artists are tempted by the elegance of modern interiors and the grace of feminine costumes.

In the 19th century there has also been much retrospective painting, particularly of the 18th century, and this has led to a very close and minute study in the works of Gainsborough in England, of Meissonier and Gérôme in France, and many other artists of ability. The retrospective tendency of our own time has been strongly manifested in other ways. The modern interest in the past has been shown by much 'historical' painting on insufficient data representing personages whose portraits we do not possess, in buildings that have left no trace, and engaged in actions known to us only by the meagre narrative of some chronicler. Art of this kind possesses no real historical interest, though the landscape skill and the composition of the picture be of the highest mark. Late years has it been in a great measure superseded by archaeological painting, skilfully practised by Mr Alma Tadema and his followers, whose object is to revive the past for us in its details as it really was by representing everyday life without much pretence to the portraiture of individuals or the recording of particular events. This kind of painting has brought the art nearer than ever to the spirit of the history of art, and with a still greater interest of it is outside of artistic interest, but there is no reason why archeological pictures should not be as beautifully drawn, as well composed, and as richly coloured as any others.

A sketch of the history of painting would not be complete without mention of the antiquity of landscape. Landscape backgrounds are found even in Assyrian art, they are not uncommon in Greek and Roman antiquity, and they attained a considerable degree of freedom and observation in the backgrounds of the paintings at Pompéii. After the death of classic art, painting began again from its first rudiments in the ornamental art of the middle ages, and the study of landscape soon revived in the backgrounds of religious pictures. Medieval landscape lasted down to Raphael, who was himself essentially an intellectual artist, and especially in his early works. The general characteristics of that kind of landscape are clear atmosphere, pure skies, either cloudless or with a few white clouds, pale blue distances with hills, green foregrounds, and almost invariably one or more well-kept buildings. The foregrounds are usually smaller, with thin twigs and few leaves visible almost separately against the sky; in the distance they may be more massive. Water is usually calm in ponds or winding rivers, or serene and beautiful in lakes. The rocks occur on the left of the landscape, but are seldom accurately represented, the medieval ignorance of rocks having even persisted in Leonardo da Vinci notwithstanding his scientific genius. In the backgrounds of Albert Dürer all kinds of objects are observed and set down as in a catalogue; he perceived the grandeur of mountains, the abundance of forest trees, the picturesque beauty of medieval towns, and he took an interest in all the details of the foreground; but he never fused his details into one connected whole; he never saw nature with the eye of a landscape-painter; he had no sense of atmosphere or effect. The beginning of the modern landscape spirit is to be sought for in Venice. Titian made many studies of landscape, and, although in his pen-drawings there is no recognition of local colour and very little effect, there is an impression of the strange beauty of the beginning of the modern landscape spirit is to be sought for in Venice. Titian goes still further and attempts transient effects, showing himself a true precursor of the modern landscape-painters. Tintoretto occasionally exercised his magnificent powers in the same direction. The most influential of professional landscape-painters was Claude. He had not the power of the Venetians, but he had a tenderness and charm, and a sense of grace and beauty, that won the hearts of contemporaries and have since maintained the celebrity of his name, though it is ever for all Landscape Titian goes still further and attempts transient effects, showing himself a true precursor of the modern landscape-painters. Turner did not manifest much personal independence until he had first studied andimitated the old masters. Turner's relation to French landscape painting is more closely connected with the past than with the future of landscape painting. He had the deepest respect for the older masters, whom he both studied and imitated, yet he founded no school and has had little influence on the art of England and none on the art of France. However, Constable, on the other hand, who during his lifetime was a less celebrated artist, has had a very far-reaching influence. The freshness and originality of his view of nature, less poetical and imaginative than Turner's, but nearer to realistic reality, determined the future direction of that French romantic school which in its turn has influenced all the schools of Europe. Whilst England has had her poet landscape painter in Turner, France has had hers in Corot, a painter of at least equal celebrity, though of much narrower range. Like Turner, Corot founded his art on the study of Claude, but won favour late in life by a delicacy of sentiment which was his own. His subjects were simple and his effects chosen so as to avoid strong colouring, but he composed beautifully and was a master of quiet rhythms, and of indifference.

Since the middle of the 19th century landscape painting, both in oil and water-colour, has been actively practised all over Europe. Every class of society has found its interpreters. Scotland has been painted effectively by Horatio MacCallum, Scottish Mr Peter Graham, Mr Colin Hunter, and many others. A severely accurate and scientific spirit was imported into English landscape by Mr Cooke and Mr Brett. The French landscape of the present day is usually marked by simplicity of subject, breadth of treatment, and truth of tone, with one or two rare exceptions. Marine painting in all countries appears to concentrate their attention more than their predecessors upon the sea itself, and both English, French, and American artists have produced remarkable studies of waves.

A sketch of the history of painting seems to require a brief enumeration of the sects which have divided artists. The chief of these have been the Classics, the Romantics, the Realists, the Pre-Raphaelites, and the Impressionists. The classical aim was the pursuit of the ideal, which was believed to be one and to have been attained by Homer and Raphael, and exemplified by the French painter Ingres. The Romans desired freedom from the classical restraint, and liberty to illustrate all literature and all history that interested them in their own way; their great man was Eugene Delacroix. The doctrine of the Realists is the right to represent persons and things as they are without beautifying them by idealisation. This doctrine was at one time represented by the French painter Courbet; but, in fact, there was a great deal of downright realism long before his time as well as in Velasquez, Rembrandt, Teniers, Ostade, Hals and Hobbema, and it had of course an influence upon the impressionists. Raphael's idealism was not alone in its return to the painstaking imitation of detail which marked the practice of Raphael's predecessors. Like the continental movements in the same direction, it was a return to patient analysis and had a disciplinary value; but the accumulation of art experience was too much for it. After Titian, Velasquez, and Reynolds, it is not possible to blind down the art of painting permanently to the minute practice of the early masters. Intellectually the movement was of more importance, as it favoured the choice of noble subjects. Impressionism asserts the importance of visual artists, especially Turner and Constable, as their predecessors. They are equally opposed to the detail of the minute painters and to the hard, clear, linear definition of the classical schools. There can be no doubt that theoretically they have right on their side, but in practice their art is often indiscreet, and the great benefit of art and most rapid sketching to be successful, with great certainty in selection and perfect truth of tone.

The present state of the art of painting is one of complete freedom from all the former restraints of religious or classical authority. The fine arts are as free as the sciences, and, although less exclusively devoted than men of science to the pursuit of natural truth, contemporary painters at least refer to nature for everything. The consequence is a pervading freshness in the modern schools, and it is also certain that manual skill has never been so general as it is now. On the other hand, the intensity of the commercial struggle amongst the great multitude of artists is certainly not favourable either to learning or to refinement, and it is doubtful whether painting makes any advance in taste and culture corresponding to the increase of its productivity or the extension of its fields of study.

Chronology.—The extent of the subject renders inconceivable treatment unnecessary. Archaic Greek drawing, marked by want of proportion, especially in the thickness of limbs, lasts in vase-painting throughout the 5th century B.C. and later. The 6th century B.C. is of great importance, and the 5th century better drawing on many vases; in 4th century it is often learned and beautiful, as on Camirus vase (British Museum), contemporary with Protogenes. Attitudes then easy and graceful, faces shown in all positions; 5th and 4th centuries B.C. golden age of antique painting, including Apollodorus, Zeuxis, Parrhasius, Apelles, Polygnotus, and Micon. Romans imported Greek pictures and took up painting by imitation, Roman painter Ladas (Augustan age) anticipated Claude in many of his pictures. Paintings preserved at Herculaneum and Pompeii, especially the frescoes, belong nearly to Christian era, some earlier, others a few years later. Pompeian painting shows interest in ordinary life and in landscape. Classical art is, in feeling and principle, prolonged for six centuries in the service of Christianity.

The middle ages are divided by Wolfflin into (1) Early, from 700 to 1500 A.D.; (2) Romanesque, from 950 to 1250 A.D.; (3) Gothic, from 1250 to 1400 A.D. Thus the three periods are 250, 300, and 150 years. Throughout these ages, speaking generally, the human figure of art is religious, and its artistic motive is ornamentation. At the same time the figure design began again from a barbarous infancy, it being necessary for the representation of religious personages. From 8th to 12th century childish drawing and gaudy colouring prevailed throughout Europe. But the partial improvement takes place, and in 14th the advance is noticeable. By Cluny and Clas Sisler art was developed to life-like statues. Brothers Van Eyck (q.v.) born in this century.

The 15th century is the time of transition from the art of the middle ages to an improved draft of drawing and colouring preparatory to the Renaissance. Improvement is seen in France, the Netherlands, Flanders and Italy. Van Eyck's work known in southern Europe, his influence only technical, and soon died out in Flanders itself. Roger van der Weyden.
Schools Flemish painting. 1594—French also Snyders 1697-1764 Italy as the 1615—Lesueur the 1590-1649) work; Frans the Vouet those also minutely perfection. 1509-86) position Roger Sarto (1414-93), Ghirlandajo 79), gives school Roman affect Venetian; Paduan, 1376). 1530-88). contemporary, 1600 centurj'. 1532). (1483-1511), Pietro (1452-1519), Michelangelo (1478-1511), Leonardo (1452-1519), (1450-99), (1475-1563), 1600-82) and northern European societies send their art-students to Paris as once they went to Rome. Schools are no longer national, the art has become cosmopolitan to a degree impossible for literature.
Technical Chronology. — 400 B.C., white-lead. The history of this date has been written by Sir John Sinclair RA, 3958. Prepared in China as now; 1393-1400, true brass used by the Venetians in Italy; 1505, oil-painting generally adopted; 1710, Prussian blue discovered by Drieschel of Berlin; 1787, zinc white supplied by the firm of De Dij; 1789, Gericault discovered cobalt blue; 1814, discovery of green emeralds; 1814, the first discovery of existence of artificial ultramarine, and prussine for its manufacture soon afterwards won by Guimet of Lyons, 1814-1820; capascum brown found on Lord Audley’s estate; 1827, cadmium discovered; 1839, first discovery of existence of artificial ultramarine, and prussine for its manufacture soon afterwards won by Guimet of Lyons, 1839-1840; 1834, staining with and Van Dyke, 1830-1835; water-color painting introduced. Of the ten centre-panels of the subscription to Professor Church’s restricted palette six have been discovered during the 19th century.

Paisiel,l, Giovanni (1741-1816), a Neapolitan composer. Besides more than ninety operas (including a Barbiere di Siviglia), Paisiel,l composed over a hundred masses, requiems, and cantatas.

Paisley, a manufacturing town of Renfrewshire, stands on the White Cart, 3 miles above its influx to the Clyde, 7 WSW. of Glasgow and 16 ESE. of Greenock. Although commonly identified with the Vanduara or Vinogarola of Polone, which Skene places rather at Loudoun Hill in Ayshire, it first is heard of certainly about 1157 as Passelth, a possession of Walter Fitazon, the first Scottish ancestor of the royal Stewarts (q.v.). He six years later founded here a Cistercian priory, which was dedicated to SS. James, Mirin, and Milburgo, and which in 1219 was raised to the rank of an abbey. It was burned by the English in 1297; suffered much at the Reformation in 1561, and with the town of Paisley now and now is represented chiefly by the aisle Decorated nave (13th century: the Abbey parish church, restored since 1862), and by the chapel of St Mirin, called the “Simming Aisle” (1499), with the altar-tomb of Marjory Bruce. Near the abbey are statues of Wilson the painter (1773), and Wilson, who, like Professor Wilson ("Christopher North"), were natives of Paisley. There are also fine statues of George A. Clark, founder of the town-hall, and (since 1891) of Sir Peter and Thomas Coats. Motherwell and Alexander Smith were residents; and the latter describes the town well in Alfred Hogart’s Household. Elderslie, 2 miles W., is the traditional birthplace of Wallace.

The public edifices include the municipal (former county) buildings (1818); new sheriff court-house (1883); the fine Clark town-hall, Italian in style, and built in 1879-82 at a cost of £110,000; the new county buildings (1891), containing one of the finest council halls in Scotland; the Coats free library and museum (1872), with a picture-gallery and an observatory; the grammar-school (1576; rebuilt 1864); and the Neilson educational institution (1892). The Coats Memorial Baptist Church (1894) is, it is claimed, the finest ecclesiastical edifice built in Scotland since the Reformation, having cost £100,000. The Fountain Gardens (1888), the Brodie Park (1877), and St James’s Park, round which is the racecourse, have an area respectively of 6, 22, and 40 acres.

The linen, lawn, and silk-gauze industries, important during the 18th century, are now extinct; as, too, are the ‘Paisley shawls,’ so celebrated between 1805, and the middle of the century, their sale sometimes exceeding £1,000,000 per annum. The manufacture of linen sewing-thread, introduced in 1722 by the witch-denouncer Christian Huygh, the shawl manufacturer, has been nearly superseded since 1812 by that of David Sang. Its assumed gigantic proportions, the two principal firms now employing about 10,000 hands between them. There are also works for dyeing, bleaching, tartans, woolen shawls, carpets, distilling and brewing, chemicals, starch, corn-flour, preserves, engineering, &c., besides shipbuilding yards. The Cart since 1786 has been rendered navigable; its water-way being finally deepened to 12 feet in 1888-90; and water-works (1834-90) furnish 6,000,000 gallons per diem to Paisley and Johnstone. Paisley was made a free burg of burghary in 1488, the fourth centenary of that event in 1888 being graced by the presence of Queen Victoria, who afterwards placed a memorial of the Stewarts in the ruined choir of the abbey. Since 1833 it has returned one member to parliament. In 1843 the corporation had to suspend payment, nor was the burg clear of debt until 1877. The census of 1871 showed 21,324; (1841) 48,125; (1891) 56,927; (1901) 64,370.

See Cosmo Innes’ Registrium Monasteriis de Paised (Maitland Club, 1832), two works by Semple (1872-74), Our Cameron’s Last’s of Paisley (1878), and Robert Brown’s Paisley (1879).

Pakhol, a seaport of China, opened to foreign trade in 1756, stands on the northern shore of the Gulf of Tungking. The harbour is shallow. Trade does not flourish. The imports—cottons, woolens, opium, rice—average £600,700 per annum; the exports—tin, sugar, indigo, aniseed, hides, ground-nut oil—£220,700. Pop. 25,000.

Palma, |Francis, a Bohemian historian, was born 14th Jan. 1798, at St Boslavitz, in Moravia, and studied at Prasburg and Vienna. In 1829 he was appointed historiographer of Bohemia, and was charged to write a History of the Bohemian People to 1526 (5 vols. 1836-67), which appeared in both the German and Bohemian; it is one of the greatest literary productions in the Bohemian tongue, and nationalist through and through. Palma took part in the political agitation of 1848, and was the leader of the Slav or national party as opposed to the German at the Diet of the Kremsier. Besides his great History he published works dealing with the Hussite period, and with A. Wolfenbäck edited The Oldest Memorials of the Bohemian Language (1840). He died 26th June 1876 at Prague.

Palaeography is the science which deals with ancient manuscripts, teaching us not only to

Decipher them, but to judge of their date, genuineness, and place of origin. While Epigraphy (see the article INSCRIPTIONS) is concerned with writings engraved or written on stone or metal, the materials for paleographic study comprise ancient books, either rolls, (omitted), written on leather or papyrus, or codices, written in book form on sheets of vellum or paper. Wax-tablets, charters, bills, decrees, acts, business papers, and similar documents have also to be considered by the student of paleography.

The oldest extant manuscripts come from Egyptian tombs, and are written on sheets of Papyrus (q.v.), prepared from the pith of a rush. A few fragments date from the time of the early empire, the most important being the Papyrus Prisse, the oldest book in the world, which was found in a tomb of the 11th dynasty, and must therefore be older by several centuries than the Hebrew Exodus. Coming down to the 18th and 19th dynasties, papyrus rolls, usually containing portions of the Book of the Dead (q.v.), are numerous. But documents written on papyrus, a very fragile material, have mostly perished, and the chief ancient MSS. which have come down to us are written either on parchment, which is still used for legal documents, or on vellum; the skins being prepared so as to be written on both sides, thus superseding the older leather rolls, still used in Jewish synagogues for copies of the Law. The necessary limits of this article make it impossible to discuss the hieratic and demotic papyri from Egyptian tombs, or any of the Eastern scripts, Chinese, Pall, Indian, Coptic, Syriac, Hebrew, or even the insignificant specimens of Persian and Arabic calligraphy preserved in oriental libraries. The student may, however, be referred to the oriental series of the Paleographical Society, to Silvestre's Palaeographie Universelle, and Burnell's Elements of South Indian Palaeography. It must here suffice to describe briefly the Greek and Latin style, and the more important of the medieval scripts.

Both in Greek and Latin manuscripts we find two contemporaneous but widely-different styles of writing: a book-hand, formal and stiff, but legible, used by professional scribes, and a cursive hand, rapid, careless, loose, and straggling, often very difficult to read, which was employed for private correspondence, contracts, accounts, and, somewhat formalised, for charters, rescripts, and other official documents.

The book-hands may be classed as Capital, Uncial, or Minuscule. The capitals, which differ little from the lapidary forms used in inscriptions, are square and angular, such as are still retained for initials, titles, and superscriptions. Manuscripts written wholly in capitals are very rare, the use of more facile materials, such as parchment or papyrus, having led at a very early time to modifications of the lapidary forms, transforming them into uncials, a formal book-hand, large, clear, and legible, used by professional scribes for codices, and derived from the capitals with little change, save that the forms are more rounded, and often inclined rather than upright. Thus, ε both in Greek and Latin is a characteristic uncial form, obtained by rounding the capital form E, and saving labour by requiring only two strokes of the pen instead of four. The term Uncial is as old as the time of St Jerome, but its modern usage is due to a misconception, uncial letters being seldom an inch in height, as the name implies. The general resemblance in the character of Greek and Latin uncial will be seen by a few words from St John, xxi. 19, as they appear in the Codex Bezae at Cambridge, a manuscript assigned to the 6th century, containing the Gospels and Acts in Greek, with the Vulgate translation.

**CHMENON TOI LONATATNAKFACEITONON**

**SIGNIFICANSQUAMOMERTENHONORIFICABITIM**

Greek.

Or, in ordinary minuscules, σημείων [σημείων] των θανάτων δόξαν τον Θεόν, 'significans qua morte honorificabimus Deum.'

In the 8th and 9th centuries a new book-hand was evolved mainly out of the cursive, but incorporating sundry forms from the degenerate contemporaneous uncials. This, by reason of the smaller size of the letters, is called minuscule. The old majuscule cursive, developed out of the capitals and uncials, which had by this time become formless and illegible, was gradually superseded by a new cursive, developed out of the minuscule. The minuscule reached its perfection and a book-hand in the 10th century, after which it continually degenerated till the invention or printing. Both for Greek and Latin books the early printers adopted at first the corrupted forms of the contemporary book-hands, but afterwards returned to the older and purer types of the 11th and 12th centuries. Thus there is a general analogy between the successive stages of Greek and Latin writing. Side by side with the old cursive scripts there is a gradual evolution of improved uncial book-hands till about the 4th century, followed by a period of decay, till the 9th century, when the revival of learning produced a regeneration, again followed by progressive deterioration till the invention of printing caused a reversion to the best of all preceding styles, that of the 11th century. Traces of these revolutions may still be recognised. It will be observed that we now employ four different alphabets: minuscules for our printed books, and capitals for their titles, pages, headings, and initials, and cursive for our correspondence, while the initials in our ordinary writing are analogous to uncials. Familiarity prevents us from noting the wide differences in the forms of such letters as A, n, a; B, b, b; G, g, g; or R, r, r. These are survivals, the first from the lapidary capitals of the Augustan age, the second from the French book-hand of the 11th century, and the third from the Tudor cursive, modified and improved by the Italian cursive of the Elizabethan age.

Greek Paleography.—No Greek manuscripts written in pure capitals have come down to us, though the transitional forms may be detected. The oldest Greek manuscripts now extant are papyri in early uncials of the Ptolemaic period which have been found in Egypt, their preservation being due to the dryness of the climate, and to the practice of burying documents in tombs. Three must be earlier than 100 B.C., and there are several Hellenistic fragments on ostraca earlier than the Christian era. The most important contain Orations of Ilyricides, of which the oldest are assigned to the 1st century B.C. We have from Herculaneum an ancient library consisting of 1893 papyri rolls, which must be older than 79 A.D.
The deformed uncial and the earlier cursive, from each of which it borrowed certain features. The earliest trace of these minuscule forms as yet discovered are seen in a collection of papyri, ranging in date from 302 to 616 A.D., which were the business and family papers of Aurelius Pachyimus, a dealer in purple dyes. The transition from the old to the new style is excellently exemplified in a manuscript sheet of papyrus from Ravenna, now at Vienna, which contains the signatures of certain bishops to the Acts of the Council of Constantinople, held in 680. The older bishops sign in shutting uncials and the younger men in early forms of the new minuscule. In the 9th century, with the current of learning, this new minuscule developed into a calligraphic book-hand, which was used in veurnum codices. The oldest books in which it appears are the Uspensky Gospels, written in 833, and the Bolleanus Codex of 888 A.D. The chief transformations are due to the use of ligatures, as is plainly seen in the forms of the letters α, ι, and η. Hence in the fully-formed minuscule of the 11th century we find the letters a, e, η, φ, ω, which follow the old uncial forms, while δ, ζ, η, θ, are taken from the new. In the case of several letters the double source of their form is apparent, the retention of duplicate forms, β, θ, τ, and τ, for instance, being uncials, while δ, ζ, η, and θ are of cursive origin.

From the end of the 12th century to the invention of printing the minuscule continually degenerated, losing its purity and beauty, and breaking up into a rough cursive script. The writing becomes intricate and involved, ligatures and accents being combined into a single character rapidly executed without taking the pen from the paper, making the writing very difficult to read. In the earliest printed books these contracted and ligatured forms of contemporary minuscule MSS were faithfully imitated. These, however, were gradually discarded, though a few, such as ς for σ, ε for ϝ, and σ for σ, survived till quite recent times.

Latin Paleography followed much the same course as the Greek. There were four set book-hands—capital, uncials, minuscules, and ligatures. The last two were influenced by the old Roman cursive. The capitals are of two kinds, Square and Rustic. Square capitals differ little from the lapidary characters used in inscriptions, and may be defined as having their vertical and horizontal strokes at right angles. Of the few examples we possess of this script the best is the St Gall Virgil, assigned to the 4th century. Rustic capitals, which were characterized by circumflexed finalis and by the crossbars being curved and slightly oblique. This style, which can be traced in a Herculaneum papyrus of the 1st century A.D., was greatly in fashion from the 5th century to the 7th. Good examples are four famous Virgils—two of 6th century, a 7th century, and a 9th century. The Rustic died out about the 9th century, and left no successor.

The uncials arose out of capitals, and exhibit rounded forms of certain letters. The earliest uncial codices extant are not earlier than the 4th century A.D., but it is plain that uncial
writing was practised at an much earlier period, since we find uncial forms in some of the Graffiti (q.v.) scribbled on Pompeian walls, while as early as the 3d century B.C. the lapidary forms of P, R, C, S show that uncial influences had already transpired. The Graffiti contain also these letters. The uncial book-hand is distinguished from the contemporary square capitals by the rounded forms \( \epsilon, \omicron, \omicron, \upsilon, \upsilon \) instead of \( E, M, V, H \), and by the tails of \( P, F, Q \), and \( R \) falling below the line, while the head of \( L \) rises above it.

One of the oldest uncial Latin MSS. is the Ver- celle Gospels, said to have been transcribed by the hand of Eusebius himself, but in any case nearly as early as his time. A good example of the later uncials is the copy of the Gospels now in the library of Corpus Christi College, Cambridge, which is believed to have been the actual copy brought from Rome by St. Augustine in 596. Also of the 6th century is the Codex Bovae at Cambridge, the style of which is shown in the fac-simile already given. The earlier and later uncial styles are well seen in the manuscripts with a monogram of Bobbio, now in the Vatican. A manuscript of the 12th century is a manuscript from which the writing was washed off with a sponge, or sometimes scraped or rubbed, in order that the vellum might be used for some other work. The Codex Ephraemi above mentioned is a palimpsest, and is written on the leaves of a manuscript written in a 12th-century hand. The Vatican Cicero is a codex consisting of 150 leaves, containing in the first hand the treatise De Republica, written in double columns in large uncial, probably of the 4th century. Over this is written the commentary of St. Augustine on the Psalms, in a small uncial hand of the 7th century.

The old uncial script is derived from the early uncial, which in its turn is derived from the cursive and cursive, which is a mixture of uncials and semiuncials, and thus a transition between the two. The semiuncials were used for writing official documents, and the uncials for religious purposes. However, the uncials were soon superseded by the semiuncials, which became more popular in the 4th century.

In the 5th century, the uncial script was still in use, but it began to decline in the 6th century, when it was replaced by the semiuncials, which were more adapted to the needs of the time. The semiuncials were used for writing official documents, and the uncials for religious purposes.

The semiuncials were used for writing official documents, and the uncials for religious purposes. However, the uncials were soon superseded by the semiuncials, which became more popular in the 4th century.
semicursive is demonstrated by the permissive use of N, B, S, which are uncials, and of n, r, f, which are uncialised cursives. Several other forms, such as g, b, m, f, l, are also uncialised cursives, and not, like the Roman uncials, merely rounded capitals (see IRELAND, Vol. VI, p. 208). This Irish semicursive style of the 8th century is a more splendid of all medieval scripts. The noblest specimen is the magnificent Book of Kells now at Dublin, which was probably written in the 7th century, though often referred to the 9th (see ILLUMINATION). Of some later Irish MSS., notably St. Liechfeld, and the Lindisfarne or Durham Book, commonly called St. Cuthbert's Gospels, now in the British Museum, both of which were written in Northumbria, where the script had been introduced by Irish missionaries. This Northumbrian semicursive formed the basis of the nearly perfect Caroline minuscule, so called because during the reign of Charlemagne it was introduced by Alcuin of York, the friend and preceptor of the emperor, into the calligraphic school at Tours, over which Alcuin presided from 778 to 804. Alcuin collected and elaborated certain elements from the Roman uncial and the Lombardic minuscule; and the new script, recommended by its legibility, distinctness, and neatness, was rapidly diffused by Alcuin's pupils over Europe, and rapidly superseded all the other monastic hands. Starting about the year 470, by the 9th century, it reached its highest perfection at the end of the 11th. In the 13th deformation set in; it stiffens and becomes more cramped, ligatures and contractions are introduced, and out of it grew the Black Letter, or later Gothic, a form of which still survives in German printed books. The black letter was used in the earliest printed books, but, with the revival of learning, Italian scholars returned to the beautiful Caroline minuscule of the 11th century, which was imitated in the Roman type presses universal in Italy, France, Spain, Britain, and America, and which is rapidly replacing the Gothic letter in northern Europe. See PRINTING.

Besides the pure Caroline minuscules used for books, various cursive hands grew out of it, more angular, irregular, and difficult. Such are the Anglo-Saxon and the pointed Irish, the Domitianic script (see DOMESDAY BOOK), and the deformed hands used in English charters and the records of courts. Our modern English script is based on this 'court-hand,' which arose out of the degraded Caroline minuscule—improved, however, in the reign of Elizabeth—to the convenience of the contemporary Italian hand. It is, however, much superior in legibility and distinctness to the modern German script, which, as we have seen, is to a great extent a survival from the old Roman cursive.

Contractions.—The difficulty of deciphering mediæval MSS. arises largely from the various contractions of abbreviations, and ligatures which were employed to economise labour and parchment. To give a complete list within reasonable limits is impossible, more especially as they varied at different periods and in the various inks. More than 3000 contractions of Latin words were used in France between the 7th century and the 16th, while in England more than 1000 are found in official Latin documents of the Tudor period alone. There are, for instance, six recognised contractions for quomiam, seven for each of the other abbreviations. In one MSS. stands for quomiam, in another for quom, while.Q denotes quomodo in one script and quomium in another. Instead, therefore, of attempting to catalogue the more usual contractions, which are tabulated in several works referred to below, it will be more useful to explain the general principles by which medieval scribes were guided. In most cases, if not in all, these contractions arose out of ligatures, and were used at first for some particular syllable, and then as time went on they were generalised, so as to denote a whole class. Some of these ligatures we still use. Thus, w, as in Jam, is a ligature of i and m, and no explanation is needed. The two superscript dots, as in or, which express the German umlaut, are merely the ligatures aw and uw. The usual modern sign of abbreviation is the full point, as in lb, or ibid. For ibidem, e.g. for example, or ibidem, there is no ligature. This, on the other hand, seems so natural and simple a sign, appears, when we trace its history, to have arisen out of a ligature for the common Latin termination -ns. Its earlier form was the colon (:) which stood for -ns, as in omnibus. The origin of this colon is explained by the fact that at a still earlier time we find the final syllables -mus and -nus written yf and yf, where the cross stroke f, which is merely the long s, forms a ligature with the curve—which represents u. Of this ligature, representing -us, everything disappeared except the dots at the top and bottom of the s, leaving us: for -mus, or i; for nos, two dots and two strokes, and ultimately the use of the full point (:) was generalised so as to denote the omission of any final syllable. When this had taken place another special sign was required for -ns. This was 9, so that in later documents we find either cyâ, or possibly 9yâ. But in earlier MSS. the loop of the sign 9 is open at the top, the form y being manifestly the ligature of u and the long s.

In viz. for videlicit, and oz. for ounce, we have survivals of a very frequent abbreviation, which also proves to be a ligature. The z is merely used for the ends of their own words instead of the correct sign 3, which is found, by tracing it back, to be only a rapid and slurred way of writing the semicolon (;) without taking the pen from the paper. The sign at one time denoted only the omission of either of es, as in habet, or of ve, as in q; for vide. The latter, however, was originally written q: where the reversed comma (,) is the letter u, and the dot stands for e, as in many other cases, such as -n: for cum, or for est. This ligature was assimilated to the nearly identical ligature ( jot, or guillemet) used in MSS. to signify the omission of the final syllable, as in oz for ounce, or in the apostrophies signs ( or , for and , for dehors). The sign 3 for script is merely the ligature er, the long s being crossed by a cursive r.

The superscript comma now used to denote the omission of medial syllables or letters, as in can't for cannot, or I've for I have, was at first merely a superscript r, and denoted exclusively the omission of r or of a syllable containing r, such as er or re. In English records it forms a ligature with the preceding letter, as in font for furent, vbo for vero, etc., etc. in acce

The circumflex (~) grew out a cursive form of the mucial m, and originally denoted exclusively the omission of m, then of n, and afterwards of other letters. Thus we have omis, omis, and omen for omnis, habi and habi for habet, and s for non. The acute line (') is one of the earliest signs of omission, and in some cases, if not in all, is merely a simplified form of the circumflex, as in for enm, or for autem, or for omnis. Its use was, however, less restricted than that of the circumflex, and we still use it in the contraction B for libra (pounds), the
double bar in £ denoting a double omission. Shil-
lings and pence, now expressed by s, and d, were for-
merly denoted by d and ℒ, abbreviations for solidi
and denarii. The sign $ for dollars is said to be the ligature cursive m, formed by the Dutch
form of d (but see DOLLAR). The circumflex (~)
which was a cursive m was not always written horizon-
tally. We see this in the common sign ą used for
roman, as ąngor or ąvang or ąverom, and ąvə or ąverom. Here
ą is the ligature of ą and ł, which is crossed by n in
the cursive form (~) or (~) when written vertically.
For ąt there are numerous signs, all of which resolve
themselves into ligatures. Some of them, such as
ąę, ął, and ąć, require no explanation. They
are found in ąs for enschaft, and in the various forms
ąv, ąvă, ąvădă, ąvădăcă, ąvădăcăcă, ąvădăcădăcă for ąvădăcădăcă,
which we now use for ąvădăcădăcă.
For ąt there are numerous signs, all of which resolve
themselves into ligatures. Some of them, such as
ąę, ął, and ąć, require no explanation. They
are found in ąs for enschaft, and in the various forms
ąv, ąvă, ąvădă, ąvădăcă, ąvădăcăcă, ąvădăcădăcă for ąvădăcădăcă,
which we now use for ąvădăcădăcă.
Many similar contractions were also used, most
of which can be easily resolved into ligatures. A
few of the more common are ą for pro, p for per and
pex, v for quae, v for good, ą for qui, a for iz, fr for frater, \( \frac{1}{2} \) for ser
and si. Thus we have supi and supis for
superius, ppe for prope, pę for propeius, gelof for
generosi, na for asseto, fil for filz.

BIBLIOGRAPHY. — The study of Paleography requires
either an ample purse or access to a good library, the
needful works being mostly bulky and costly. The best
books of moderate price for the beginner in Greek Paleo-
graphy are Wattenbach's Anleitung zur Griechischen
Paleographie und Schriftarten, and Gardthausen's
Griechische Paleographie. For Latin Paleography
it would be well to begin with Wattenbach's
Anleitung, and Arndt's Schrift-Tafeln. For Medieval
Paleography, Chasseria's Paleographie der Chretien und
Manuscripten, with his companion volume, Dictionnaire
des Abreviations du Moyen Age, are extremely useful
little books. Prou's Manuel de Paleographie may also
be recommended. For Charters and MSS. in general, say-
ning Mr Maunde Thompson's long-promised work, has
had to fall back upon Wright's Court-Hand Restored,
published in 1773, and the article 'Records' in Savage's
Dictionary of English Antiquities. The evolution of the
ten formal letters is traced in Dr Taylor's book on The Alphabet.
Subsidiary matters, such as writing materials, gatherings,
lining, punctuation, &c., which are useful in
determining the age of MSS., are discussed in the woks of
Gardthausen and Gardthausen already mentioned, and also in Watten-
bach's Schriften in Mittelalter, and Lent's Urkunden-
lehre. Of the more costly works, far the most important
are the autotype fac-similes published by the Palaeo-
graphical Society, with Zangemeister's Ezecnum Codicis
Laevanum, Wattenbach's Ezecnum Codicis Graecorum,
and his Scriptum Graecum Specimen. For MSS. in England,
the MSS. in Bodleian Library, and the MSS. of ancient
masters, and of MSS. in the British Museum must be consul-
ted; for German MSS., Sybel's Works and Sieckel's Monumenta Graecina;
for Russian, Sabat's Specimen Paleographiae; for Italian, the Archivio
paleografico Italiano; for Spanish, the Exempla scriptura
visiqtica; for French, the Notices et Extraits des
Manuscriptes, and the valuable publications of Delisle and
Le Roy; for American MSS., the important works of
Walther's Lexicon Diplomaticum, Walby's Éléments
de Paleographie, Astle's Origin and Progress of Writing,
Silvestre's Palaographie Universelle, Montfaucon's Paleog-
raphie, Conrady's Recueil de Textes Diplomatiques,
and the Benedicte Nouveau Traité de Diplomatique.

PALEOLITHIC. See ARCHAEOLOGY, FLINT IM-
PLEMENTS, STONE AGE; also MAN.

PALEOLOGUS, the name of an illustrious Byzan-
tine family, which first appears in history about
the 11th century, and attained to imperial dignity
in the person of Michael VIII. in 1260 (see BYZAN-
TINE EMPIRE). The last of the dynasty, Constant-
ine XI., fell bravely fighting at the siege of
Constantinople by the Latin forces under
Morea and of Achalza respectively; a daughter of
one of them married Ivan III. of Russia. A branch
of the family ruled Montferrat from 1306 to 1533.

PALEOLOGY (Gr., 'study of ancient life'), the science or study of fossil organic remains—
 whether of animal or plant life. The study of fossil animals was sometimes called
that of fossil plants palaeophytology. The aim
of palaeontology is to attain a knowledge of all
the various plants and animals which have suc-
cessively appeared and disappeared in the course
of geological ages. But as the geological record
is highly imperfect, and many of species which
have lived and died without leaving any trace
behind them, it is obvious that our knowledge, no
matter how enlarged it may become, can never
possibly be complete. The history is full of gaps,
some of which may be bridged over, but, however,
that may be, it is new and important work,
that our knowledge must always bear but a small
proportion to our ignorance. Nevertheless, the
study of palaeontology has been fruitful in results.
It has greatly influenced zoology and botany—and
scientists sometimes hope of perhaps finding in
fossil remains of the peculiarities of animal and
plant life—to which the light which it has thrown on the evolution
and mutual relations of existing forms of life.
Fossil organic remains consist chiefly of the harder
parts—such as bones, scales, teeth, shells, crusts,
spines, seeds, hard fruits, and also the trunks of
plants (see FOSSILS). In attempting to interpret
the evidence supplied by such remains, palaeonto-
ologists were early led to study, for purposes of com-
parison, the structures of existing plants and
animals. By applying the results of these compari-
sons to the restoration of extinct forms of life,
Cuvier was enabled to establish the law of the
'correlation of organisms,' and thus the palaeontologist,
who has to deal principally with fragmentary
remains, is not in such a helpless case as might have
been supposed. Stated in its most general form,
the law of the correlation of organisms is the law that
all the parts of an organism stand in some relation
to one another, the form and characters of each
part being more or less closely dependent on, and
connected with, the form and characters of all the
rest. In other words, an organism is not a
fortuitous collocation of unrelated parts, but is
composed of mutually adapted and related organs;
the possession of any given organ, therefore, imply-
ing the possession of other 'correlated' parts
(Nicholson and Lydekker). Hence the palaeonto-
ologist can often infer from an isolated organ or struc-
ture the essential characters of the remainder
of the organism. But, while the biological sciences
have greatly benefited, it is geology which has been
most advanced by palaeontological research. With-
out the help of a palaeontologist the geologist would be unable
to reconstruct the past. By their aid he is able to
identify and correlate the various formations which
constitute his systems. It is from them that he
infers former climatic and geographical changes—
that he is able to distinguish between fresh-
water and marine deposits, between the conditions of
the various geological systems. Here all that need be
done is to summarise the characteristic features of
the Palaeozoic, Mesozoic, Cainozoic, and Quater-
nary or Post-Tertiary faunas and floras.
Palaeozoic Life.—The most prominent types of Palaeozoic times were Graptolites, Rugose and Tabulate Corals, Pteroids, Nautiloid Cephalopods, Trilobites, Eurypterids, and Heterocercal Ganoids. Graptolites ranged from the Cambrian into the Lower Old Red Sandstone, but attained their maximum in Lower Silurian times. Rugose corals, unknown in the Cambrian, swarmed in the Silurian and Carboniferous seas, but were much less numerous in those of the Permian. Crinoids first appear in the Cambrian, are numerous in Silurian and Devonian rocks, but more abundant still in the Carboniferous. After this they begin to decline. Trilobites, common in the Cambrian, abound still all through Palaeozoic times, but culminated in the Upper Silurian period. They were still numerous in Devonian and Carboniferous seas, but less abundant in those of the Permian period. Pteroids were more common in Upper Cambrian and Silurian times during Devonian and Carboniferous times. Nautiloid Cephalopods first appear in the Upper Cambrian, and seem to culminate in the Silurian, but they continued to abound in the Devonian and Carboniferous seas, becoming reduced in those of the Permian period. Pteroids, which first in the Cambrian, reach a maximum in the Silurian, wane in the Devonian and Carboniferous, and die out in the Permian. They are therefore essentially and characteristically Palaeozoic forms. So likewise are the Eurypterids, which, culminating apparently in the Upper Silurian and Lower Old Sandstone, became extinct in Carboniferous times. Ganoids with heterocerai tails first appear in Upper Silurian strata, and reach their maximum in the Old Red Sandstone. The great order of Sharks and Rays likewise dates back to Upper Silurian times. Some are in the present types in Palaeozoic strata. Many other forms, however, are met with, amongst which may be noted starfishes (Asteroidea), brittle-stars (Ophiuroidea), sea-urchins (Echinoidea), and the wholly extinct and characteristic Palaeozoic types, Cystoidea and Blastoids. Amongst the crustacea were cirripedes, ostracods, phyllopods, king-crabs, amphipods, isopods, long-tailed decapods, and stomatopods. Arachnids were represented by scorpions and other forms; myriapods and insects by a number of ancestral types. All the great classes of molluscous life were present—Cephalopods flourishing from the Upper Cambrian; Pteroids in Lower Cambrian; Gasteropods in Lower Silurian; and Lamellibranchs in Upper Cambrian. The fishes have been already mentioned. Amphibians, represented by Labyrinthodonts and Salamandroids, appear first in Carboniferous strata.

Amongst plants the prominent Palaeozoic types are cryptogams—Lepidodendrales, Sigilliariidae, and Calamites being exclusively Palaeozoic, but conifers were also present.

It may be noted that many of the characteristical life-forms of Palaeozoic times were what are termed synthetic or comprehensive types, that is to say, types which while belonging fundamentally to some particular division or group of the animal kingdom, yet present in their structure characteristics of one or more other divisions, or, as yet non-existing types. Among such intermediates or comprehensive forms may be mentioned the Labyrinthodonts, which were modile amphibians with many piscine and reptilian characteristics. Examples are also furnished by the Ganoids, the Trilobites, the Brachiopods, the insects, &c. Amongst the Palaeozoic plants, Lepidodendrales exhibit similar peculiarities, for they combine characteristics of club-mosses and conifers. Again, many Palaeozoic forms attained a larger size than the corresponding forms that belong to later times. Thus, some of the pterods, cephalopods, ostracods, phyllopods, and insects were as large as anything produced in our own day. The amphibians likewise exceeded in size any living representatives of their class.

Imnumerable Palaeozoic genera died out before Mesozoic times, while not a few lived on, and some have even persisted to the present day. These persistent forms are met with abundantly in the lower types of animal life, as foraminifiers, brachiopods, and molluscs. See CAMBRIAN, SILURIAN, OLD RED SANDSTONE, CARBONIFEROUS, and PERMIAN SYSTEMS.

Mesozoic Life.—The life of Mesozoic times is in many respects strongly contrasted with that of the Palaeozoic era. In place of Sigilliariidae and Lepidodendrales, the prevalent forms of plant-life up to the close of the Cretaceous period were arborescent and herbaceous ferns, conifers, and cycads, while in late Cretaceous times the earliest angiosperms appeared. Corals, which were plentiful in Mesozoic seas, consisted almost exclusively of modern types—the rugose corals having waned almost to extinction. Echinoids and starfishes abounded, but Crinoids, so prevalent in Palaeozoic seas, were now much reduced in number. Some of the higher grades of the crustacea, which are hardly known in Palaeozoic rocks, were plentiful in Mesozoic times, and the same was the case with insects. Brachiopods ceased now to be dominant forms; while amongst molluscs the Cephalopods take the lead, and reach their culminating type in the Jurassic Belemnitidae. Gasteropods and Lamellibranchs are well represented, and include a number of modern genera, which increased towards the close of the era. Ganoids were still numerous, mostly with symmetrical tails. Chiroptera true sharks, and rays were all known, while the numerous bony fishes made their first appearance. Labyrinthodonts, which in Triassic times attained a great size, soon died out, making way for the advent of a prodigious reptilian fauna, in which all orders, save the Ophiurida, were represented. There were mammalia, reptilia, (Ichthyosaurus, q.v., Plesiosaurus, q.v.), flying reptiles (Pterodactylus, q.v.), snake-like reptiles (Dinosaurs, see DINOEUTHRIA), crocodiles, and cheloniens. This reptilian life was especially abundant in Jurassic times. Birds probably were numerous, some of the forms being toothed, while others were of a higher type. Mammals were represented by only the inferior grade of marsupials, and were all of small size. All the remarkable reptiles referred to became extinct before the beginning of the Cainozoic era. So it was with the characteristic Mesozoic molluscan families of Ammonite, Belemnite, and Hippurite. Putting aside the lowly organised Protozoan, it may be said that hardly one Cainozoic species has been met with in Cainozoic or Tertiary strata. See TRIASSIC, JURASSIC, AND CRETACEOUS SYSTEMS.

Cainozoic Life.—The plants of early Cainozoic times, although differing specifically and often generically from living forms, yet approach on the whole to existing types. Palms were a common feature of the flora from Eocene into Pliocene times. They were introduced into Europe during the early Eocene, but later on forms characteristic of the warmer latitudes of North America began to abound. A commingling of Indo-Australian and American types also marked the Oligocene period, but the American forms were generally the most slowly replaced by the types preponderated over all the others. The Pliocene flora of central Europe had a prevalent Mediterranean character. With regard to the lower forms of animal life, all that need be noted here is the general fact that these have a modern aspect, the
number of existing genera and species becoming greater as we advance from the lower to the higher stages. The foraminifers attained now their maximum development, and are characteristically represented by the large coin-shaped mammalites. Amongst these, and especially Cretaceous, are not infrequently found the most dominant forms—the most abundant groups being Lamellibranchs and Gasteropods. But the most striking and leading Cainozoic forms were the mammals. In Eocene times the mammals were greatly developed—many of the forms attaining a large size. Among the more notable types of the early European Tertiary are Palaotherium (q.v.), Anoplotherium (q.v.), along with which were carnivores, rodents, insectivores, and bats, and also the earliest representatives of the horse and the monkey tribe. The Tertiary mammals are marked by the appearance of Dinotheres, Mastodonts, true elephants, rhinoceroses, hippopotamuses, deer, antelopes, gazelles, various carnivores, such as Machairodus, bears, cats, wolves, &c., and apes. No certain or unequivocal evidence of man is yet forthcoming from Tertiary strata.

While it is true that the general aspect of the plant and animal life of the Cainozoic era approaches to that of the present, yet this is truer for the less highly organised types than it is for those which are higher in the scale of being. Amongst the higher the division of early Tertiary there still persists a few possessed characters which are now met with only in widely separated forms. Some, for example, were intermediate in character between tamarins and horses; in others (Tillodonts) we meet with a combination of structures now seen in ungulates, rodents, and carnivores, which by no longer of the carnivores had decided marisonal affinities. Other remarkable composite forms were the Dinosauria (q.v.).

Quaternary or Post-Tertiary Life.——The animals and plants of Quaternary age form for the most part to existing species; a number of the higher vertebrates, however, are extinct. Among these latter, in Europe, were the Mammoth and various other animals, several rhinoceroses, a dwarf form of hippopotamus, and Machairodus. In North America the fauna also included various extinct species, such as Mastodon, an elephant, and several gigantic members of the Sloth family (Megatherium, Mylodon, Megalonyx). These last seem to have abounded in South America, where they were associated with great armadillos (Glyptodon). The Quaternary character is marked by marked oscillations of climate, and consequently by secular migrations of flora and fauna. Thus numerous forms which had survived from the Tertiary era eventually became extinct, and a still larger number were banished from the areas which they had occupied in Pleistocene times. It is in the deposits of the Pleistocene that we meet with the first unquestioned relics and remains of man. See Pleistocene System, Postglacial and Recent System; works cited at Geology; and the special literature on the subject. See also palus (new ed. 1879), Seeley (1885), Steinmann and Didlerlein (1888), Zittel (i.-iii. 1870-90), &c.

Palaeotherium (Gr., 'ancient wild beast'), a genus of pachydermous mammalium whose remains occur in the Eocene beds of England and the Continent. Several species have been described, ranging from a form that inhabited a region similar to that of modern Europe, to a hog-like form. The Upper Eocene gypseous gourries of Montmartre supplied the first scanty materials, which Cavier, by a series of careful and instructive inductions, built up into an animal resembling the existing tapi. The restoration, however, is not quite correct, for the discovery of a complete skeleton (P. magnus) shows that the animal was longer-necked, and of a more slender build than the tapi, and probably was not unlike, in general appearance, the living llama. There can be no doubt, however, that Palaeotherium resembled the tapi in having the snout terminating in a short proboscis. It had three toes on each foot, each terminated by a hoof. The formula of the teeth is i. i., c. 1, p.m. 2-3, m. 3, and the structure of the upper true molars, in certain particulars, seems to foreshadow that of some of the Equidae.

It is supposed that animals of this genus dwelt on the margins of lakes and rivers, and that their habits were similar to those of the tapi.

Palaeozoic (Gr., 'ancient life'), the name given to the lowest division of the fossiferous rocks, because they contain the earliest forms of life. They were formerly, and are still generally, known as the Primary rocks. The strata included under these titles are the Cambrian, Silurian, Devonian and Old Red Sandstone, Carboniferous, and Permian systems.

Palafox y Melzi, José de, Duke of Saragossa, a Spanish soldier, was born in 1780 of a distinguished Aragonese family, and rose to the rank of brigadier-general in the Spanish guards. His defence of Saragossa (q.v.), 22d July 1808 to 21st February 1809, which only yielded to the French after a second investment, is one of the most heroic incidents in modern history. Palafox y Melzi was carried prisoner to France, and not released until 1813. The year after his return home he was appointed captain-general of Aragon, in 1830 was created Duke of Saragossa, and in 1837 graced by the Crown of Spain, was placed in general command of the guards. He died at Madrid, 15th February 1847.

Palagonite-tuff, usually associated with basalt lavas, is fine-grained, red, brown, and sometimes greenish or yellowish in colour. Under the microscope it is seen to be composed of minute fragments of volcanic glass, crowded amongst which are granules and crystals of augite, olivine, plagioclase, and magnetite. It occurs in Sicily, the Canary Islands, the Faroe Islands, Iceland, and Scotland. See Igneous Rocks.

Palanpur, capital of a native state in Gujarat, lies 53 miles N. of Ahmedabad by rail. The state has an area of 3150 sq. m., and a pop. of 254,402. The 'Palanpur Agency' comprises, besides Palanpur, twelve other small native states.

Palaquin, or Palki, an Indian vehicle corresponding somewhat to the Roman litter and the modern European sedan-chair, but, unlike the latter, used for long distances by travellers where railways or good coaching-roads do not exist. It is a wooden box, about 8 feet long, 4 feet wide, and 4 feet high, with wooden shutters which can be opened or shut at pleasure, and constructed like Venetian blinds. At each end of the palaquin, on the outside, two rings are fixed, and the women, or palanquin-bearers, of whom there are four, at each end, support the palaquin by a pole passing through these rings.
Palapteryx (Gr., 'ancient apteryx'), a genus of fossil birds whose remains are found in the river-silt deposits of New Zealand, associated with the gigantic Dinornis, and which, like it, resembled in the form of the sternum, and the structure of the pelvis and legs, the living wingless apteryx. Palapteryx, however, seems to have possessed rudimentary wings. See Mio.

Palaye. See Shoshong.

Palate, the roof of the mouth, consists of two portions, the hard palate in front and the soft palate behind. The framework of the hard palate is formed by the intermaxillary bones, the palate processes of the superior maxillary bones, and by the horizontal processes of the palate bones, and is bounded in front and at the sides by the alveolar arches and gums, and posteriorly is continuous with the soft palate. It is covered by a dense structure formed by the periosteum and mucus membrane of the mouth, which are closely adherent. Along the middle line is a linear ridge or raphe, on either side of which the mucus membrane is thick, pale, and corrugated, while behind it is thin, of a darker tint and smooth. The membrane is covered with scaly epithelium, and is furnished with numerous follicles (the palatal glands). The soft palate is a movable fold of mucus membrane enclosing muscular fibres, and suspended from the posterior border of the hard palate so to form an incomplete septum between the mouth and the pharynx; its sides being blended with the pharynx, while its lower border is free. When occupying its usual position (that is to say, when the muscular fibres contained in it are relaxed) its anterior surface is concave; and when its muscles are called into action, as in swallowing a morsel of food, it is raised and made tense, and the food is thus prevented from passing into the posterior nares, and is at the same time directed obliquely backwards and downwards into the pharynx.

Hangman from the middle of its lower border is a small conical pendulous process, the uvula; and passing downwards from the uvula on each side are two curvial folds of mucous membrane containing muscular fibres, and called the arches or pillars of the soft palate. The anterior pillar is continued downwards to the side of the base of the tongue. The posterior pillar is larger than the anterior, and runs downwards and backwards to the side of the pharynx. The anterior and posterior pillars are closely united above, but are separated below by an angular interval, in which the tonsil of either side is lodged. The tonsil consists of a number of scattered organs of a rounded form, which vary considerably in size in different individuals. They are composed of an assemblage of mucus follicles, which secrete a thick grayish matter, and open on the surface of the gland by numerous (twelve to fifteen) orifices. The space left between the arches of the palate on the two sides is called the cisthena of the ferces. It is bounded above by the free margin of the palate, below by the tongue, and on each side by the pillars of the soft palate and tonsils.

As the upper lip may be fissured through imperfect development (in which case it presents the condition known as hare-lip, q.v.), so also may there be more or less decided fissure of the palate. In the slightest form of this affection the uvula merely is fissured, while in extreme cases the cleft extends through both the soft and hard palate as far forward as the lips, and is then often combined with hare-lip. When the fissure is considerable it materially interferes with the acts of sucking and swallowing, and the infant runs a great risk of being strangled; and if the child grows up its articulation is painfully indistinct. The closure of cleft palate by operation must be left in the hands of an experienced surgeon, who should be called to see the child as soon as the defect is noticed. If the separation is too great to admit of closure by operation, or 'artificial palate' may be made to cover the opening.

Acute inflammation of the tonsils, popularly known as Quinsey, is treated of in a separate article. Chronic enlargement of the tonsils is very frequent in scrofulous children, and is not rare in scrofulous persons of more advanced age, and may give rise to very considerable inconvenience and distress. It may occasion difficulty in swallowing, confused and inarticulate speech, deafness in various degrees from closure of the Eustachian tubes (now often termed throat deafness), and noisy and laborious respiration, especially during sleep; and it may even cause death by suffocation, induced by the entanglement of viscid mucus between the enlarged glands. If local and constitutional remedies fail to reduce the enlarged tonsils they must be more or less removed by the surgeon, either by the knife or by the guillotine specially invented for the purpose.

Enlargement or relaxation of the uvula is not uncommon, and gives rise to a constant tickling cough and to expectoration, by the irritation of the larynx which it occasions. If it will not yield to medical treatment, it may require to be removed either in whole or in part.

Palatinatc (Ger. Pfalz), the name for two German states, which were united till the year 1623. They were distinguished as the Upper and Lower Palatinate. The Upper or Bavarian Palatinate, now forming a circle of the kingdom of Bavaria, was a duchy, its capital being Amberg. The Lower Palatinate, or the Palatinate on the Rhine, lay on both sides of the Rhine, with an area of 3150 sq. m., and included, besides the Electoral
**PALATINE**

Palatinate proper, the principality of Salmiers, the duchy of Zweibrücken, the principalities of Veldenz and Lautern, &c. was bought by Maximilian, Trèves, Lorraine, Alsace, Baden, and Würtemberg. Its capital was Heidelberg.

The counts of the Rhenish Palatinate were established in the hereditary possession of the territory of that name, part of the land attached to it, as early as the 11th century. In 1211 Frederick II was granted to the Duke of Bavaria, and with various combinations the Rhenish Palatinate and the Bavarian territories were held by members of the Bavarian house and its branches. Sometimes the electoral dignity was exercised by the Duke of Bavaria and the holder of the Rhenish Palatinate. In 1559 the Rhenish Palatinate and the electoral vote passed to Frederick III., who introduced Calvinism. Frederick V. (q.v.) was the 'Winter King' of the Thirty Years' War, who in 1623 lost his lands to his kinsman the Duke. Bavaria retained the Upper Palatinate and the electoral dignity; but the Rhenish Palatinate was in 1648 given to Frederick's son, and the eighth electorate created for him. In 1694, during the war of the Spanish Succession, the electorate received again the Upper Palatinate, and all the electoral rights, resumed again by Bavaria after the war. During this time the Rhenish Palatinate was repeatedly and cruelly desolated by French armies; and in 1901 France took possession of all the left bank of the Rhine, giving the rest to Bavaria, Nassau, and Hesse-Darmstadt. In 1816 the left bank was restored to Germany, the larger part of the Lower Palatinate being granted to Bavaria (Rhenish Bavaria); Prussia got the Rhine Province; Hesse-Starkenburg and Rhine Hesse; and Baden Mannheim and Heidelberg. Most of the privileges of the palatinate has been successively Catholic, Lutheran, Calvinist, and Catholic again, in accordance with the tenets of the reigning prince. For the area and population of the modern Upper and Lower Palatinate, see BAVARIA.

**Palatine** (from Lat. palatium, 'palace'). A Cones Palatines, or Count Palatine, was, under the Frankish kings of France, a high judicial officer (see COUNT), his district being called a palatinate or county palatine. In England Chester and Durham became palatine under William I., doubtless on account of their respective proximity to the frontiers of Scotland and Ireland. Chester had not only its own courts, judges, constables, and stewards, but a parliament, and was not represented in the national parliament until 1549; it was assimilated by Henry VIII. Durham ceased to be a county palatine under its bishop in 1386. Lancaster became palatine in 1451, and yielded its jurisdiction in 1573 to the High Court of Justice (see LANCASTER, DUCHY OF). At various dates Kent, Shropshire, the Pembrookshire, the Isle of Ely, and Herefordshire, were counties palatine, but had lost their special rights by the 16th century. Of similar privileges in early Scotland, the Earls Palatine of Strathaven held the most important.

**Palatine Hill** (Mons Palatinus), the central hill of the famous seven on which ancient Rome was built, and, according to tradition, the seat of the most Roman settlements. See ROME.

**Palawan** is the western island of the Philippines (q.v.). Area, 2815 sq. m. Province, long and narrow, with an axial mountain-chain, and has extensive and well-protected bays and harbours. The soil is fertile, yielding the products of the archipelago. Capital, Puerto Princesa. Pop. 45,000.

**Pale** [Irish history (see IRELAND, Vol. VI, p. 294)] is the oldest of the kingdom over which the English rule and law was acknowledged. It varied very greatly at various dates, but for a long period meant generally Dublin and the greater part of the adjoining counties.

**Palembang**, capital of a residuary (formerly an independent kingdom) near the south end of Sumatra, stands on the river Musi at its mouth; the houses of the town are built on great log rafts on either bank. Manufactures, trade in silk goods, carved wood, ornaments in gold and ivory, and krisses, as well as shipbuilding, are carried on. In the middle ages Palembang was one of the most important centres of Arabian trade with China. Pop. 43,368; and of the residency, 627,419.

**Palencia** (the ancient Pallantia), a walled city of Spain, in Old Castile, stands in a fruitful plain, 180 miles by rail NNW. of Madrid and 29 NNE. of Valladolid. The Gothic cathedral was built 1291-1504. The first university of Castile was founded here in 1208, but was removed to Salamanca in 1239. Blankets and coarse woollen cloths are manufactured. The vine is cultivated, and there is a good trade in wool. Pop. 14,565.

The province of Palencia has an area of 2326 sq. m. and a Pop. (1887) of 188,924.

**Paleque, RUINS OF**, lie between the Michi and Chacunas rivers, in the north of the Mexican state of Chiapas, 64 miles E. of the village of Santo Domingo de Paleque. The ruins extend over 20 to 30 acres, and are buried in a dense tropical forest; trees grow over and about the buildings, and rise even from the tower. The ruins consist of vast artificial terraces, or terraced truncated pyramids, of cut stone, surmounted by edifices of peculiar and solid architecture, also of cut stone, covered with figures in relief, or figures, &c., with hieroglyphics in stucco, with remains of brilliant materials. Most of the buildings are at one story, but a few are two, three, and some may have four stories. The principal structure, known as the Palace, is 228 feet long, 180 feet deep, and some 25 feet high, standing on a terraced truncated pyramid of corresponding dimensions; the front contained fourteen doorways, each about 9 feet wide. The building was irregular, and built in two distinct parts, with double galleries of unequal length running round it, and two large courts, also irregular in shape. Charnay holds that the Palace was magnificently colonnaded; Paleque, he says, was a holy city, 'a place of demons' teeming with shrines and temples, a vast and much-sought burial-place;' in the whole place 'there seems to have been nothing but temples and tombs.'

See Stephens' *Incidents of Travel in Central America, &c., and Catherwood's Views of Ancient Monuments, &c.; Charnay's Ancient Cities of the New World (Eng. trans. 1887); also La Rochedouan,f, *Paleque et la Civilisation Maya* (Paris, 1888).

**Palermo**, formerly the capital of Sicily, now in point of population the fifth city of Italy, an archbishopric, and a seaport. It stands in the north-west corner of the island, on a bay that faces east, and at the mouth of a fertile valley called the Conca d'Oro ('Golden Shell'), 120 miles by rail W. of Messina, and occupies a picturesque site, being backed by mountains—the coast being by Mount Pellegrino, with a (pilgrimage) grotto chapel (1624) to St Rosalia, whose festival is one of the great annual events of the city. The streets are for the most part handsome, and there are many fine old buildings. The city was founded at date from the Norman period, and belong to two styles of architecture—Saracenic and Byzantine. The most conspicuous of them all is the cathedral of St Rosalia, built (1169-83) by an Englishman, Archibishop Walter; it contains sepulchral monuments to Roger I., the emperors Henry VI. and
PALERMO

Frederick II., and in the crypt the tombs of the archbishops. Others to be named are the chapel (1143) in the royal palace, with magnificent mosaics; the Norman hall, a fine specimen of the same style; and the college of the Chartreuse (with fine mosaics), St John of the Hermits (1132), and St Cataldo; and the mansions of Zita, Cuba, La Favara, and Min-nerno, all outside the city. There are close upon three hundred churches and chapels in Palermo. The royal palace, built by Roger I., is principally of Spanish architecture; in it Pizzaro established his observatory. The other public buildings—archbishop's palace, town-house, law-courts, university, arsenal, &c.—do not call for particular mention. The university (1447) has 70 teachers and 1100 students, with schools of engineering, fine arts, conveyancing, &c. There are also a national museum, the town library (1775) with 141,000 vols. and 2640 MSS., and the national library (1804) with 110,000 vols. and 12,000 MSS. Industry is little developed; machinery, essences, sumach, tanner, iron-founding, books, gloves, and shoes represent almost the only branches. But Palermo is an important seaport, with a large, though not growing, trade. Oranges, lemons, dried fruits, sumach, tartar, grain, oils, manna, sulphur, wine, animal produce, and lemon-juice are exported, and only 12,000 tons per annum. The imports—grain and vegetables, cottons and woolens, coals, live-stock, iron, timber, groceries, silk, hides, petroleum, machinery, linen, metals, and glassware—fell from £1,439,515 in 1877 to £762,167 in 1889. The bulk of this trade is with Great Britain, France, and the United States. There is also a coasting trade—imports, from 3 to 3½ millions sterling; exports, about 1 million sterling. Some 3500 vessels of 1,200,000 tons enter every year, an average of 430,000 tons last year, and 453,690 in 1889. Pop. (1894) 276,000.

The first we know of Palermo, the ancient Panormus, is that it was a Phoenician city, and the stronghold of Carthage in Sicily. It was conquered successively by Pyrrhus (276 B.C.), the Roman (214 B.C.), the Vandals (440 A.D.), Belisarius (533), the Saracens (827), the Pisans (1093), and the Normans from Apulia (1071). Henceforward it was the capital of the kingdom of Sicily (q.v.), first of the Norman kingdom, then of that of the Angevins and their Spanish successors. It suffered severely from earthquakes in 1712, 1756, 1782, 1818, 1823. The siege of Palermo by the Bourbon kings of Naples in 1820 and 1848, and was freed from them in 1860 by Garibaldi. But since then it has been only a provincial capital. — The province of Palermo has an area of 285 sq. m. and a pop. (1885) of 819,765.

See the excellent guidebook of Gass Feli; Moro, Descrizione di Palermo Antico (1827); Schubring, Historische Topographie von Panormus (1870); Springer, Mittelalterliche Kunst in Palermo (1889); Holm, Stati di Sicilia (1891); Fergusson, Historical Essays (54 series, 1872), and his History of Sicily (1891).

PALESTINE

I. History.—The name of Palestine is an illustration of the part taken for the whole. In the song of Moses (Exod. xv. 14) sorrow falls upon Palestine, and amazement upon Edom at the coming of Israel. Palestine was to Moses as it was afterwards to Isaiah and to Joel, to Hesiodus, to the Valesian, to the Saracens, to the Genoese, to Josephus and to Jerome, simply the Plain of Philistia, the broad slip of coast inhabited by the Philistines. Milton restricts the word to this sense. The country has received various names at different times; all of which we are familiar. It has been called Canaan, or the Land of Canaan, the Land simply, the Land of Israel, the Land of Promise, and the Holy Land, a name, which in the words of Quaresimius, 'though of later date than the rest, yet in excellence and dignity surpasses them all.'

The nations inhabiting this country at the time of the conquest were, according to the list generally given, six in number. A seventh nation is added in one or two lists. These nations were the Canaanites, the Hivites, the Hitites, the Amorites, the Perizzites, and the Jebusites. The seventh were the Girgashites. The Canaanites—lowlanders—occupied the country east and west of the highlands—that is to say, the seaboard and the valley of the Jordan; the Hivites, a branch of the great kingdom whose extent and history are only now beginning to be recovered, dwelt in what was afterwards Judea, the Hivites in Samaria, the Perizzites in Galilee, the Amorites in the north, the Jebusites in and around Jerusalem. Of the Girgashites nothing is known. Other tribes there were—those of Mourn, Ammon, Midian, and Edom on the east of Jordan, all of Semitic descent; the tall races—Rephaim, Zznim, and Amukina; the Horin cave-dwellers; and there were the Amalek- sites, who defended the mountain-passes near Sini, and the Philistines, of Egyptian origin; in later times they were called Carchemishites, and at this day there is a village in Philistia called Keretinya.

The flood of conquest rolled over these tribes. When Israel had settled down within the boundaries allotted to them, we find them fighting for their new possessions, being driven back in consolidating their position. The conquered peoples were nowhere exterminated: the Jebusites held their own in Jerusalem, the Amorites in Ephraim; the Philistines took and lost and retook Gaza and Ascalon. There are many who regard the fellaheen of modern Syria as the direct descendants of the Perizzite, the Amorite, and the Hivite.

How long the Israelite tribal distinctions were kept up is difficult to say. We find them strongly marked in the early history, but they begin to be lost in the later books. It is not without significance that Solomon's twelve provinces corresponded mainly with the twelve tribes. During the term covered by the Book of Judges and part of Samuel there was no capital city and no central authority. The religious centre was shifted from Shiloh, at Nob, at Giloeon, and at Bethel. Jerusalem became the capital of David and Solomon, but on the foundation of the northern kingdom Shechem, Tirzah, and Samaria became successively its capital, and reunited to it the cities of the north and west.

When the Jews returned from the great Captivity they occupied a territory extending from Jerusalem in the north to Beersheba in the south, and from Jericho in the east to Lachish in the west. The Philistines remained in undisturbed possession of their lands; the Idumaeans were driven back to their deserts; on the north were the hostile Samaritans.

The Macenean struggle for independence—a part of history which finds few students, yet a struggle heroic in its conduct and stupendous in its results—showed the nations existed that there were Jews in the time of Herod, that there are Jews still, is due to the heroism of the immortal brothers.

The kingdom of Herod the Great covered the whole country divided into tribes by Josha, with the exception of Idumaea, which was assigned to the tribe of Asher in the north. West of Jordan it contained Galilee, a province unknown by that name to the Old Testament; Samaria, also unknown before the Captivity; Judea and Idumaea; east of the Jordan it contained Perea, Canaan, and the territories of the ten tribes of the northern kingdom. The towns of the Decapolis belonged partly to Perea and partly to Gaulonitis. Of these provinces the most fertile and the most densely populated was
Galilee. He who takes the trouble to examine the large map of the Palestine Exploration Fund and to compare with it the statements made by Josephus will be astonished at the overwhelming evidence of a vast population and of exorbitant fertility. Nowhere else in the country are there so many ruins of ancient towns; on every hill-top in a country which is a succession of hills is a Khurbet or ruin; springs abound; there are the traces of ancient terraces on the hillsides, extensive heaps of pottery, ancient cemeteries, broken oil-presses, groups of rock-hewn cisterns; proofs on all sides of the ancient prosperity.

This period of prosperity, encouraged by the Roman rulers, was destroyed by the madness of the Jews themselves. It vanished with the campaign of Vespasian and with the destruction of the temple by Titus. Even these rude lessons failed to quell the fiery spirit of the people. A second time they rose in revolt, not only in Judea, but also in Egypt, Cyrene, Babylonia, Cyprus, and Mesopotamia. They were subdued. But again, when Hadrian endeavoured to suppress altogether this turbulent Judaism, there followed a rising, the wildest, the most blood-thirsty of all the Jewish revolts. It was led by Bar-Coeliba (q. v.), 'Son of the Star,' the pretended Messiah, whose pretensions and profanities were a marvel even to the most learned of all the Jewish doctors. The rebellion was followed by a siege of Jerusalem, concerning which history is almost silent. It was probably marked by all the horrors which belong to the siege by Titus. The last stand was made at the fortress of Bethler, when Bar-Coeliba, with an immense number of his followers was slain.

Then for a period Jerusalem vanished from history. It is Elia Capitólon; a temple of Jupiter was erected on the site of Herod's temple; no Jew was allowed to appear even within sight of the Holy City. Outside, for the next hundred years, though persecutions raged, the progress of Christianity was rapid and continuous; pilgrimages began to the holy places, and as a natural consequence the Holy Land in a continual state of uneasiness. The Samaritans gave trouble from time to time by murdering Christians; they were quieted in the usual manner, by punishment. All Syria became a nest of monasteries, nunneries, and hermitages. In order to build their monasteries the old synagogues, the old fortresses, were destroyed and their stones used again. In every cave was a recluse; on every hillside lived a hermit; some erected lofty pillars and levied the taxes upon them; others set the discovery of relics, holy bones, and holy places went on without interruption. Day and night, it is said, the air resounded with litanies. In a word, the land was given over to monks, for whom the country-people—the descendants of the Perizzites and the Amorites—filled the fertile soil, grew the corn, pressed the oil, and made the wine.

Then King Chosroes, the Persian, marched into Syria (614 A.D.). The Jews, who had been quiet, but were neither dead nor converted, raised their heads in hope and gladly joined his victorious army. What the Persians did in the country itself may be guessed from the fact that in Jerusalem alone they massacred 90,000 Christians (the number may be taken as indicating a gigantic slaughter) and destroyed the whole of the buildings. When they retreated they left behind them along the broad track of their march, nuns' and monks' monasteries destroyed by hundreds, with thousands of dead Christians to rejoice the eyes of the Jews who followed in the train. Fifteen years later Heraclius reconquered the province of Syria. The ruined churches were partly restored, the monasteries partly rebuilt. But for six years only, for then followed an enemy worse than Chosroes, because, though the Persian destroyed, he went away. The new-comer came to stay. In the year 626 A.D. the caliph Omar with his Moslems took Jerusalem and prepared to reduce the whole of the country, which indeed offered no resistance. After three hundred years of the ecclesiastics followed four hundred years of the Moslems. Jew and alike tolerated; the latter with a little less contempt than the former. Early in the Moslem period, the Dome of the Rock ('Mosque of Omar'), the most beautiful building in the world, was erected for Abd el Melek by Byzantine architects. The church of the Holy Sepulchre, the group of churches bearing that collective name, was completed and beautified. We hear nothing more, however, of the monks. They disappeared at the first approach of the Mohammedans, and were no more seen. Except for the invasion, in 1244, by the Chorasiunians (or Kharizmins; see KIHYA), then followed a period of peace for the country. It was a period of continual pilgrimages. Men from all parts of western Europe visited the country, and knelt weeping at the places which had seen the sufferings of the Lord. And year by year while men related how these places where miracles were wrought daily were in the hands of the infidels, who cursed and reviled the Christian pilgrims, the indignation grew until the world was ripe for the Crusades.

The Latin kingdom of Jerusalem began in the year 1099, and lasted less than a hundred years, except in name. But it took two hundred years before the Christians were finally driven from the coast of Syria, and longer than that before the

Mosque of Omar, Jerusalem.
The character and occupation of the country are shown by the fact that the only mineral wealth is in the form of salt and limestone, the former being found in many places, and serving as a source of revenue. The greater part of the inhabitants live in the country, and are主要从事农业 and commerce. The country is divided into two main divisions, viz., the Jordan Valley and the Coastal Plain.

The Jordan Valley is a narrow valley, about 50 miles long and 10 miles wide, bounded on the north by the mountains of Bashan, on the south by the mountains of Edom, on the east by the mountains of Moab, and on the west by the Dead Sea. It is a region of great natural beauty, and is the seat of many important establishments. The Dead Sea, which is the lowest point on the earth, is the principal feature of the valley.

The Coastal Plain is a broad and fertile region, lying between the Mediterranean Sea and the Jordan Valley. It is a region of great agricultural importance, and is the seat of many important establishments. The ports of Jaffa and Gaza are the principal centres of trade in the region.

The climate of the country is mild and temperate, and is characterized by a long summer season.

The vegetation of the country is abundant and varied, and includes a wide range of plants and trees. The flora of the country is rich in medicinal plants, and includes many species of herbs and spices.

The fauna of the country is also abundant, and includes a wide range of animals. The wildlife is rich in game, and includes many species of birds and mammals.
are only locally abundant, but are quite sufficient to enable us to refer the beds either to the Cretaceous or Eocene periods. (3) The great depressions of the Jordan valley and Dead Sea, known as the Ghôr, lie along the line of a great fault, or dislocation of the strata, owing to which the strata do not correspond to each other on opposite sides of the valley, but are vertically displaced; being let down on the west and elevated along the east. This is most noticeable along the eastern margin of the Wady-el-Arabah, and in Palestine its position is marked by the abrupt uprising of the tableland along the eastern side of the Jordan Valley and the Ghôr. The valley itself on either side is often diversified by terraces of sand, sand and gravel, with lacustrine or fluvialitic shells, and of rock-salt along the western margin of the Dead Sea. These terraces are at various levels above the present waters of the valley, and reach to a height of about 1200 feet above the Dead Sea surface in the 'Arabah Valley. As they are also lake-deposits they indicate that the waters of the Dead Sea once rose to a level of 1200 feet higher than at present, thus forming a lake which must have had a length of 120 miles from north to south, embracing the Sea of Galilee and the Jordan as far as the Dead Sea, and probably promoting the territory called El Lissan (or 'The Tongue'), which juts out into the Dead Sea from the base of the Moabite escarpment, as well as the corresponding terrace of rock-salt capped by gypsum marl on the west side of the Dead Sea, are portions of a once continuous land of this most ancient and vastly the extensive inland lake. (4) Along the east of the Jordan Valley and Dead Sea the base of the Cretaceous limestone is seen reposing upon variegated sandstone, known as the 'Nubian Sandstone' of Lower Jordan, the surface of which is marked by varicolored crystalline rocks, such as granite, gneiss, porphyry, and schist, of great geological antiquity. Of these rocks the flanks of the Edomite Mountains are composed, as well as those forming the Sinaïtic peninsula. In the valley of the Nile the same series reaches the surface at the First Cataract, and is seen to pass below the Nubian sandstone. Everywhere these crystalline rocks are the foundation of all the geological formations of this region, and have been referred to the Archæan or Laurentian period. The Cretaceous and Eocene formations of the valley are divisible into two great groups of Eolin and Moah, and extend eastwards under the great elevated plain of the Arabian Desert, a counterpart of the Libyan Desert west of the Nile. From the neighbourhood of Kerak northwards these limestone strata are intersected or overlaid by dykes and sheets of basalt, which form the region of Trachonitis east of the Sea of Galilee, and which have been poured forth from volcanic vents and fissures in the region of the Hauran. Some of the volcanic cones and vents are remarkably perfect and resemble those of the Auvergne region in central France, both having been developed in Post-Tertiary times; and it is not improbable that some of the hot springs which issue forth along the line of the Jordan owe their high temperature to the proximity of the underground waters to the strata in that country. While they have benched the surface.

In the Lebanon and Hermon the Cretaceous and Tertiary limestones are thrown into numerous flexures, and are repeated by successive faults, amongst which the most important is the prolongation of the Lebanon Valley and Dead Sea, known from indications which have been observed, appears to be continued along the valley of the Orantes.}

III. The Exploration of the Country.—The stream of pilgrims to the Holy Land began in the 21st century, and has never since then ceased. This stream rose to its highest flood in the century before the Crusaders, when the Mediterranean was covered with ships conveying the pilgrims to the shores of the Holy Land, and the roads were black with the troops of the warriors who walked through Europe and across Asia Minor. Those of them who returned in safety told what they had seen. Some of them wrote descriptions of the Holy Land. Thus, in the 4th century, a pilgrim from Bordeaux, who visited the country when Constantine’s basilica was being built, wrote an account of his journey. In the same century Eusebius produced an Onomasticon or gazetteer of the Holy Land. Later on Jerome, Eucherius, Theodorsen, Antoninus Martyr, Procopius, before the Moslem conquest, wrote to Abulfeda, the great geographer of the country and of Jerusalem. After the conquest the pilgrims were allowed to come and go un molested. Arbulus, Willibald, Bernard, and others have left descriptions which belong to the 7th, 8th, and 9th centuries. Moreover, the Moslems themselves formed an extensive network. A few years later Nâzîr-i-Khusran wrote an account of his journey from Balkh, through Armenia and Palestine to Cairo, thence to Mecca, through Persia, and so back to his native town. The Crusaders of the 12th century wrote accounts of their visits, their occupations, and their customs, while the descriptions and narratives of pilgrims who wrote in Latin, French, Russian, Greek, Hebrew, Persian, and Arabic throw floods of light on the country and its history. Many of them, while they lack the accuracy of later geographers, but they convey instruction as regards the land and its physical features, which is correct as far as it goes. Thus the map of Marino Sanuto indicates the hill-country, the mountains of Libanus, the River of the Desert, the survey of the country and of the Inland Sea. And the surveying, place the towns with a reasonable degree of accuracy. Palestine, therefore, though never explored, was tolerably well known to the world, as well known as Italy was formerly to the French or the Low Countries in the English. Modern exploration, with fuller knowledge of what was wanting, began in the 19th century with Scoton, Burekhanlî, Buckingham, Irby and Mangles, Tupper, De Saulcy, Van de Velde, and Williams. The researches of Robinson and the immense additions made by the late Sir Richard Lander in the geography of the country of the years 1858-52 forced upon the world the necessity for an exhaustive survey of the county. Robinson demonstrated the existence everywhere of ruined towns and hill-forts in which were preserved the long-lost names of Bible places. It became certain that a triangulation of the country, such as that of the Ordnance Survey of Great Britain and Ireland, which should leave not a corner of country, not a single hillside, unexplored, would be fruitful in results, and would furnish a map of such accuracy as to require no more books or maps. The physical features of the country were already known in general terms, but the details were mostly unknown; while even the curious foot-steps of Robinson had left whole tracts of country totally unexplored. The foundation of the Palestine Exploration Fund (1865) was the first step taken in this new direction; but it shows how little the necessity for such a survey was impressed upon the minds even of its founders that they began, after a preliminary journey under Captain (Colonel Sir) Charles Wilson, by writing in Jerusalem under Lieutenant (Colonel Sir Charles) Warren. It seemed at the moment more important to settle, if possible, the site of the temple than to make clear and intelligible the whole of the Bible narrative. For this and nothing short of this has been the result of the survey. This survey
PALESTINE

has now been executed, chiefly by Major Conder, R. E. The field has been indefatigably and arduously worked, and a work which has done so much for the right understanding of the Bible in the version into English. The whole of Western Palestine is now mapped on a scale which includes every ruin as well as every spring, every watercourse, every road, and every hillside. At least 130 lost biblical sites have been recovered; by means of these the boundaries of the tribes can now be laid down; one-fourth only of the Bible names remain to be identified. The topography of Josephus, of the Talmud, of the pilgrims, and of the chroniclers has also been taken into account. Time and again important heights have been ascertained; the levels of the Dead Sea and the Sea of Galilee are laid down; all the remaining ruins have been planned and drawn; the various forms of rock sepulture have been examined and classified; the rude stone monuments have been marked, and planned; for the first time the route of invading armies can be followed, and the strategic art of the captains can be understood; native customs have been gathered; the seasons, the climate, the fauna and flora, the monuments, the inscriptions, the ethnology of the country have been collected. These things bring floods of light to bear upon the understanding of the Scriptures. Formerly the study of the Bible was confined to the books themselves, and to the literature of exegesis which had gathered round those books. To this method we now add a mass of writings on the Bible, books which fill the greater part of our libraries, books of profound erudition from which scarcely anything can be gleaned for the instruction of the people. Now, however, there are new methods. We approach the Bible armed with coins, with inscriptions on bronzes, in hieroglyphics, in Hebrew, Arabic, and in Greek; we have inscribed monuments, such as the Moabite Stone, the Siloam inscription, the stone of the temple; we have a map of the country accurate and exhaustive, a possession at all time, which will never cease to be done again; we have measurements and plans of all the ruins; we have traditions, legends, languages, customs; we have, besides, for those who come after us, a great collection of inscriptions in unknown characters containing one knows not what ancient history. Lastly, something must not be omitted, everything which has been found, or which has been achieved, in the direction of scientific exploration goes to prove the literal exactness of the historical portions of the Old and New Testament.

The present condition of the country shows the beginning of rapid changes in every direction. The Survey of Palestine was undertaken not a day too soon. In a very few years the ruins which have been figured by the surveyors, and so, in a sense, preserved for ever, will have vanished under the destructive hands of changed customs. Thousands of visitors who every year pour into the country contribute in no small degree to alter the character, the habits, and the ideas of the people; roads are being everywhere constructed in a country where up till a few years ago there were no roads. The traveler can now travel from Jerusalem to Jericho, from Jerusalem to Hebron, and from Haifa to Tiberias. A railway is in construction between Jaffa and Jerusalem; plans and surveys of another from Haifa to Damascus, by way of Nazareth, are also ready; and there is reason to think that this railway will be built. At present a new town has sprung up outside the walls; the Russians have buildings there which, on occasion, would serve for fortresses; the Jews are flocking into the city—it is rumoured that there are now close upon 50,000 Jews in and about the Holy City; the Mount of Olives is being covered with buildings. There are Jewish colonies between Hebron, Lydda, and Jaffa; there are German colonies in the same region; Circassians occupy Aunnun, and are settling in the Haunun; the people from the Lebanon are coming down from their hills and covering the country east of the Jordan. In fact, those who have travelled in the Levant in the last three or four thousand years and more must go at one time or they will never have the chance.

BIBLIOGRAPHY.—The books published on Palestine are far too numerous to be set down. But the Survey has rendered most of them practically useless. All the books published during the last thirty years in English or French in which the results are embodied in the Survey. The Survey of Western Palestine consists of eight volumes—viz. vols. 1 to iii. Memoirs, by Captain Conder and Captain Kitchener, with plans and drawings of most of the ruins; Jerusalem, by Sir Charles Warren and Captain Conder, with a portfolio of sixty sheets illustrating the excavations; the Flora and Flora, by Canon Tristram; a volume of special papers on various subjects connected with the Survey; the Name-lists, containing all the names in Arabic with the English transliteration and the translation; and the Geology of Western Palestine, by Professor Edward Hall, F. R. S.; and theShows, which have been added in an appendix. The Survey of Eastern Palestine has been advanced one volume only. These volumes contain the facts necessary for the student. Should he only want the popular results he need read the works of Sir Gerald Rawlinson, Several years work in Palestine, Hith and Mith, Spruain Stone-loue, or that of Mr. H. A. Harper, entitled The Bible and Modern Discoveries. An excellent résumé of the Survey and of the most recent researches in Conder's Palestine. A collection of early pilgrims is in course of publication by the Palestine Pilgrims' Text Society. Palestine under the Moslems, by Guy J. Strange (Palestine Exploration Fund), gives the requirements of the world for the history, political and geographical account of the country compiled exclusively from Moslem writers. See also Canon Tristram, LAND of Israel (2d ed. 1872); Socrin, Palestine and Syria (Baedeker's guide, 1878); Thomson, The Land and the Book (1859; new ed. 1898); Sir E. Temple, Palestine (1888); G. A. Smith, Historical Geography of the Holy Land (1894); bibliographies by Toher (1875) and Bollricht (1894); and Thirty Years of Work in the Holy Land (Pal. Explor. Fund, 1903). See, too, JERUSALEM, and works cited there; JEWISH, and TEMPLES.

PALESTINE, capital of Anderson county, Texas, 151 miles by rail N. of Houston. It manufactures brass and iron goods, and has a pop. (1900) of 2287.

PALESTRA, the ancient Preneste, an Italian city, 22 miles E. by S. of Rome, on the slope of an osef of the Apennines, contains the chief castle of the Prenestine family, the residence of the Barberini family, the owners after 1630. It is built almost entirely upon the gigantic substructions of the ancient Temple of Fortune, one of the greatest religious edifices in all Italy, celebrated not only for its splendour, but also for its oracle, which was consulted down to the time of Constantine. Portions of the ancient wall—Cyclopean blocks of limestone—still remain. Preneste was a member of the Latin League, until in 499 B.C. it joined the Romans. Yet it took a prominent part in the Latin war (340-338 B.C.) against Rome. Having given shelter to the younger Marius in 82 B.C., it was taken and sacked by Sulla. Its elevated and healthy situation, at no great distance from the capital, made it a favourite summer-resort of the Romans. Augustus and Tiberius frequented it; here the Emperor found it a pleasant retreat; Hadrian built there an extensive villa; and Diocletian a palace. Numerous valuable works of art and other remains have been recovered, dating principally from the 8th, and from the 3d and 2d, centuries B.C., the latter showing Phoenician influence, the latter being Roman. P.V. 3535.

PALESTRA, Giovanni Pier Luigi da, the greatest of Italian musical composers, was born at
Palestrina in 1534. He studied music at Rome under Goudimel, and in 1531 was made maestro di cappella to the Church of San Giovanni in Laterano. In 1533 he was made choirmaster of the Lateran, and in 1541 was given the similar post in St Maria Maggiore, and held it till 1571, when he was restored to his office in the Julian Chapel. The Council of Trent, having undertaken to reform the music of the church, entrusted to Palestrina the task of remodelling this part of the religious worship. He composed three masses as examples of what could be done; one of them, the Mass of Pope Marcellus (to whose memory it is dedicated), saved music to the church by establishing a type infinitely superior, in its blending of devotional with artistic feeling, to anything that had preceded it, a type which, amid all the changes that music has since gone through, continues to attract admiration. Palestrina must be considered the first musician who reconciled musical science with music. In this work he was the most important epoch in the history of Music (q.v.). He died in the arms of St Philip Neri on 2d February 1594. His compositions, very numerous, are all sacred, except two volumes of Madrigals; they have been published at Leipzig (1868 et seq.).

The authoritative Life was written by the Italian Bajini (Rome, 1828).

Paley, Frederick Archtpe, classical scholar, grandson of the author of the Evidence, was born at Easingwold, near York, in 1816. He had his education under Dr S. Butler at Shrewsbury, and at St John's College, Cambridge, but, not obtaining mathematical honours, by the regulations of the time was shut out from the classical tripos, and likewise did not obtain a fellowship. He resided, however, at Cambridge till his conversion to the Roman Catholic faith in 1846, and later from 1860 till 1874, when he was appointed professor of Classical Literature at the abortive Roman Catholic college at Kensington. He next went to live at Bournmouth, was twice classical examiner to London University and for the classical tripos at Cambridge, and continued till the sudden close of his life (1874) the arduous labours in classical scholarship. In early life at Cambridge he helped to found the Camden Ecclesiastical Society, and published books on Gothic architecture; but the important work of his life began in 1844 with the first part of his edition of Aeschylus with Latin notes. He re-edited Aeschylus for the 'Bibliotheca Classica,' as well as Euripides, Hesiod, the Iliad, and completed the Sophocles of Mr Hayley, all for the same series; and also prepared minor editions of similar works, or parts of these, for the 'Cambridge Texts' series. His Propertii et Poetae Latinae (1878) is a dexterous

and judicious work, and his Latin translations of Theocritus, and hisSelect Private Orationes of Demosthenes (in conjunction with Dr Sandys) were recognised as works of the very highest value. He published popular translations of Plato's Phaedrus and Theogonia, of the 6th and 10th books of Aristotle's Ethics, the Ode of Pindar, and the Tragedies of Aeschylus, and renderings in verse of the 5th book of Propertius and Fragments of the Greek Comic Poets (1888). Other works were a treatise on Greek Portraits (1881), Greek Myth (1881), and an unsatisfactory edition of the Gospel of St John (1887). Paley received the degree of LL.D. from Aberdeen in 1883. A sagacious textual critic and sound exegete, he left behind him traditions of a high type of scholarship, of the age when yet scientific philology was not, and German might be neglected. In his later years he adopted a late date of birth for Paley, William, a celebrated English divine, was born at Peterborough, son of a minor canon of the cathedral, in 1743. His family belonged to the West Riding of Yorkshire, and not long after his birth his father returned to his native parish of Giggleswick to become master of the grammar-school there. In 1758 he was elected a student of Christ's College, and here he lectured on systems of philosophy till his marriage in 1770 and presentation to the rectory of Mussgrave in Westmorland and the vicarage of Dalston in Cumberland, which were soon exchanged for the more profitable living of Appleby. In 1769 he was collated to a benefice in Carlisle Cathedral, in 1782 he became archdeacon, and in 1785 chancellor of the diocese. In the latter year he published his Principles of Moral and Political Philosophy, for which he received £1000. In this work he propounds his political theories in the form of a specimen of utilitarianism. He begins by adducing a series of strong objections against the popular doctrine of the moral sense, next takes up the question of the source of obligation, and resolves it into the will of God, enforced by future punishment, it being admitted that God has power to enforce his virtue on the next world. The will of God, in so far as it is not rendered explicit by revelation, is to be interpreted by the tendency of actions to promote human happiness, the benevolence of the Deity being assumed. Objection may fairly be taken to the principle on which the morality of God is laid down, but the lucidity and appositeness of his illustrations are beyond all praise; and if his treatise cannot be regarded as a profoundly philosophical work, it is at any rate one of the clearest and most sensible of a writings, even by an Englishman. In 1790 he appeared his most original work, How Pauline, the aim of which is to prove, by a great variety of 'undesigned coincidences,' the great improbability of the common hypothesis of the unbelief of that day, that the New Testament is a cunningly prepared fraud. He seized on the idea of the famous View of the Evidence of Christianity, in which dexterous use is made of Lardner's Credibility and Bishop Douglas' Criterion of Miracles. The treatment is on the historical method, flanked by auxiliary arguments drawn from the superior morality of the gospel, the originality of Christ's character, and the like. But the bases of controversy have now entirely shifted, and the work, able as it is, is no longer, even at Cambridge, regarded adequate as a defense. The champion of the faith was splendidly rewarded. The Bishop of London, Sir John Lightfoot, in 1788, made a substantial present of £1000 and the rectory of Peterborough, and after he was made deacon of Lincoln, with £700 a year; Cambridge conferred on him the degree of D.D.; and the Bishop of Durham presented him to the rectory of Bishopwearmouth, worth £1200 a year. Perhaps his last literary achievement was his unspiritual remonstrance, as well as such homely sarcasms as comparing the 'divine right of kings' with the 'divine right of constables,' may have hindered him from yet higher preferment. After 1800 he became subject to a painful disease of the kidney, yet in 1802 he published perhaps the most widely popular of all his works, Natural Theology, or Evidences of the Existence and Attributes of the Deity, largely based on the Religious Physician of Nieuwenty, a Dutch disciple of Descartes. An excellent edition is that by Lord Brougham and

A complete edition of his works was published by one of his sons, the Rev. Edmund Paley (7 vols. 1825); later editions are those by Wayland (5 vols. 1837) and Paxton (5 vols. 1881). The best biography is that by G. W. M. Reynolds (1869); a condensed account of his life, English Thought in the Eighteenth Century (1871).

**Palghat**

a town of Malabar district, 86 miles SE. of Calicut by rail. Its old fort was of great strategic importance during the wars with Hyder Ali and Tippoo Sahib. Pop. (1891) 30,481.

**Palgrave, Sir Francis,** historian, was born in London in July 1783, the son of Meyer Cohen, a Jewish stockbroker. He was privately educated, and showed a quite remarkable precocity, having at eight translated into French a Latin version of the Battle of the Frogs and Mice, which his father printed in 1797. His father's fortunes failing in 1803, he was articled as a solicitor's clerk, and here he remained until 1822, when he took chambers in the Temple and was employed under the Record Commission. On his marriage (1823) he assumed his mother-in-law's maiden name of Palgrave. He was called to the bar in 1827, and soon acquired considerable practice in pedigree cases before the House of Lords. As early as 1818 he had edited a collection of Noreen, or Religious Poems, and in 1831 he contributed a History of England to the 'Family Library;' and in 1832 he published his Rise and Progress of the English Commonwealth, also Observations on the Principles of New Municipal Corporations. The same year he was knighted. From 1833 to 1835 he served on the Municipal Corporation Commission, and in 1835, on the reconstruction of the Record Service, he was appointed deputy-keeper of Her Majesty's Records, an office he held till his death at Hampstead, 6th July 1861.

Besides the works already mentioned, Palgrave edited for the government the following: Calendars of the Treasury of the Exchequer (3 vols. 1856), Parliamentary Writs (1830-31), Roll of Currie Regis (1835), Ancient Kalendars and Inventories of the Treasury of Her Majesty's Exchequer (1835), and Documents and Records Illustrating the History of Scotland (1857). In his private capacity he produced the Merchant and the Friar [Marco Polo and Friar Bacon], and a learned and valuable History of Normandy and of England (4 vols. 1851-61).

**Palgrave, Francis Turner,** a gifted poet and critic, eldest son of the preceding, born in London, September 28, 1824. He was educated at Charterhouse School, became scholar of Balliol College, Oxford, and Fellow of Exeter, filled for five years the office of vice-principal of the Training College for Schoolmasters at Kneller Hall, was private secretary to Earl Granville, an official of the Privy council, professor of Poetry at Oxford in 1856-59, and was a contributor to the present work. He died 25th October 1897. His works are Idyls and Songs (1841), Idyls of Art (1842), Hyman (1847), The Five Days' Entertainment at Wentworth Grange (1864), Lyrical Poems (1871), and the Visions of England (1881). He is best known, however, as the editor of the admirably selected Golden Treasury of English Lyrics (1850; 51 series, 1860), the Treasury of English Sacred Poetry (2 vols. 1875); The Sonnets and Songs of Shakespeare (1877); Selected Lyrical Poems of Herrick (1877), of Keats (1885); and Treasury of Sacred Song (1889).

**Palgrave, Sir Henry Gifford Palgrave,** another son of Sir Francis, born in Westminster, January 24, 1826, was educated at the Charterhouse School and Trinity College, Oxford, graduating with great distinction in 1846. Next year he obtained a commission in the Bombay Native Infantry, which, however, he soon resigned to become a priest in the Society of Jesus. After a course of study at Laval in France and at Rome he was sent to Cairo to study the ancient records of Egypt, which he acquired a wonderful intuitive knowledge of. Summoned to France in 1860 by Napoleon III. to give an account of the Syrian massacres, he went disguised as a physician on a daring expedition at the emperor's expense through central Asia; and traversing the Thibetan kingdom, and returning to Europe through Bagdad and Aleppo (1862-63). With the consent of the emperor, he published his Narrative of a Year's Journey through Central and Eastern Asia (2 vols. 1868), one of the best and most serviceable works on the English language. Palgrave quitted the Society of Jesus in 1864, and was sent by the British government in 1865 to treat for the release of Consul Cameron and the other captives in Abyssinia. He was nominated consul at Sukhum-Kalé in 1866, at Trebizond in 1867, at the island of St. Thomas in 1873, at Manila in 1876, and consul-general in the principality of Bulgaria in 1878, and in Siam in 1880. He was appointed British minister to Uruguay in 1884, and died at MonteVIDEO, September 30, 1888. His other works include Eastern Eastern Enterprize; Agha: an Eastern Narrative (2 vols. 1872); Dutch Guinea (1876); Ulysses: Studies in Many Lands (1887); A Vision of Life (1891, unfinished).

**Páli,** the sacred language of the Buddhists (see INDIA, Vol. VI. p. 102). Páli ceased to be a living language of India when Buddhism was rooted out of it; it was carried by the fugitive Buddhists to other countries, especially Ceylon, Burma, and Siam; but in these countries, too, it had to give way before the native tongues, in which the later Buddhist literature was composed. See the Páli grammars of Mineyevst (St. Petersburg, 1872; Eng. trans. Maulmain, 1882), Kuhn (1875), and Müller (1885); Chitt's Páli Dictionary (1875), and Frankfurter's Páli Handbook (1882).

**Páll,** the commercial capital of Jóh pur (q.v.), 45 miles by rail SE. of Jóh pur city.

**Palka,** a place on the coast between Peking and its port on the Peiho. Here in 1899 was fought an engagement between the Anglo-French troops and the Chinese, and hence the French general, Cousin-Montban (1796-1878), who was minister of War in August and September 1870, received his title of Count Palka.

**Palkars,** a name for the Arnòtades (q.v.).

**Palimpsest.** See PALEOGRAPHY.

**Palindrome (Gr. palin, 'backwards,' and dromos, 'a running'), the name given to a kind of verse very common in Latin, the peculiarity of which is that it may be read backwards as forwards. A few examples will suffice.

Sì bene tu tòrìs iuxìt: uns haút frende.
Èt nevìct ager omnì non Roma rege lacènte.
Romì regè sùa non amòs ager aìum.

A Greek palindrome, sometimes inscribed on English fonts (e.g. Hadleigh and Worlingworth, in Suffolk), runs: Νῦν ὁδοίμας μη μίαν ἱππόν ('Wash my sin, and not my face only'). A Roman lawyer gets the credit of St. John Chrysostom, who first translated this palindrome as 'Give me my fee, and I warrant you free.' It is said that in the reign of Queen Elizabeth a certain lady of rank, having been compelled to retire from the court on account of some fauna, the truth of which she denied, took for her motto: Abdeta at albo, 'Retired by day.' The English language has few palindromes, but one at least is imitable. It represents our first parent politely introducing himself to Eve in these words: 'Madam, I'm Adam.' Compare Henry B. Wheatley's book.
PALLADIUM

Palladius, the name sometimes given to Rosewood (q.v.).

Palladio, ANDREA, Italian architect, was born at Vicenza, 30th November 1518. After studying the writings of Vitruvius and the monuments of antiquity at Rome, he settled in his native city, and soon acquired a high reputation throughout the country from his designs for numerous buildings in Vicenza and the neighbourhood. He is the most conspicuous of the architects who, following Brunelleschi, led the way in establishing the modern Italian school of architecture, as distinguished from the earlier Tuscan, or San Stin, style. His style, known as the Palladian, is modelled on the ancient Roman as apprehended by Vitruvius, reproducing its dignity and strict proportions, but often to the neglect of usefulness; and its buildings are constantly encumbered by a multiplicity of columns and pilasters, broken entablatures, and inappropriate ornament, even where there is real beauty of detail. The palace Barbaro, Della Ragione, Chiurigati (now the Museo Civico), Tiene, and the Olympic theatre at Vicenza; the country mansions of Capra, Maser, and Trotta in the vicinity; and the churches of San Giorgio Maggiore and Il Redentore, the façade of San Francescoco della Vigna, and several palaces, in Venice, are his greatest achievements. He died at Vicenza, 19th August 1580. Palladio wrote a work on architecture (I Quattro Libri dell'architettura, 1570, and often reprinted) which had a great influence upon the styles of his successors, especially upon Inigo Jones, the 'English Palladio,' whose notes on the book are published in Leoni's Eng. trans., (1715). The term Palladian was, indeed, long practically synonymous with excellence, and was said to be perfect in architecture. Recent Lives (in Italian) are those by Zanella (1880) and Barichella (1880).

Palladium, among the ancient Greeks and Romans, an image of Pallas, who was generally identified with Athena (q.v.), upon the careful keeping of which in a sanctuary the public welfare was believed to depend. The Palladium of Troy was especially consecrated, the god's image being given to the founder of Ilion. It has been supposed it may have been originally a meteorite (see METEOR). Ulysses and Diomedes stole the Palladium, and so helped to secure victory for the Greeks; and both Athen and Argus boasted to have afterwards secured the possession of the charm.

Palladium (sym. Pl., atom. wt. 106-2, sp. gr. 11-4) is a ductile silvery-white metal, which in its colour and ductility closely resembles platinum. It is not fusible in an ordinary furnace, but melts at a somewhat lower temperature than the last-named metal; and, when heated beyond its fusing-point, it volatilises in the form of a green vapour. It undergoes no change in the open air at ordinary temperatures; but at a low red heat it becomes covered with a purple film, owing to superficial oxidation. It is soluble in nitric and iodide acids, and in aqua regia. It combines readily with gold, which it has the property of rendering bright and white. (When it forms 20 per cent. of the mass the alloy is perfectly white.) When alloyed with twice its weight of silver it forms a ductile compound, which has been employed for the construction of small weights; but for this purpose aluminium is superior. Professor Miller states that it has been applied in a few cases to the construction of graduated scales for astronomical instruments, for which, by its whiteness, hardness, and unalterability in the air, it is well adapted; its scarcity must, however, prevent its general use for this purpose.

It was discovered in 1803 by Wollaston in the ore of platinum, of which it seldom forms so much as 1 per cent. Another source of this metal is the native alloy (termed oro podere) which it forms with gold in certain mines in Brazil; it is from this alloy that the metal is chiefly obtained.
Palladius forms with oxygen a protoxide, PO₂, which is the base of the salts of the metal; a bisulphide, PO₄; and according to some chemists, a suboxide, PO₃. On exposure to sufficient heat these compounds give off their oxygen and yield the metal. The salts of the protoxide are of a brownish color, and it is unstable.

Palladius, Rutilius Taures Emmilianus, a Roman author of the 4th century A.D., who wrote a work, De Re Rustica (On Agriculture), in fourteen books, the last of which is a poem of eighty-five elegie complete.

Palladius, St. See Scotland (Church of).

Pallas, Peter Simon, traveller and naturalist, was born 21st September 1741, at Berlin, studied medicine and natural history at Berlin, Gottingen, and Leyden, and, already famous, was in 1768 invited to St. Petersburg by the Empress Catherine. Appointed naturalist to a scientific expedition to observe the transit of Venus, he spent six years (1785-74) exploring the Urals, the Kirghiz Steppes, part of the Alani range, great part of Siberia, and the steppes of the Volga, returning with an extraordinary store of specimens in natural history. He wrote a series of works on the geography, ethnography, flora and fauna of the regions visited. He settled in the Crimea in 1796, and there he died, 8th September 1811. The Sand-grouse (q.v.) is often called Pallas's Sand-grouse.

Pallavicino, Sforza, an Italian historian, was born at Rome, 20th November 1601. Having taken priest's orders in 1629, he became in 1638 a member of the Jesuit Society, and was created a cardinal in 1639 by Pope Alexander VII. He died at Rome, 5th June 1657. Though little known of his writings, La Historia del Credito di Trento (Rome, 1656-57), intended as a reply to the equally celebrated and liberal work of Paul Sarpi, whose narrative is not altogether acceptable to Catholics.—Ferrante Pallavicino (1618-44) wrote pamphlets which bitterly opposed the papal curia and the Barberini family; and being betrayed into his enemies' hands near Avignon, he was tried, condemned by a foregone conclusion, and beheaded.

Pallice, La, a new harbour opened (1839) to receive large transatlantic and other ocean-going vessels bound for La Rochelle in France, whence it is less than 3 miles distant. It consists of an inner harbour, and an extent and area of land protected by two mole, each 1390 feet long.

Puller, Sir William, C.B., was born at Dublin on 18th June 1839, and entered the army as a cavalry officer. In 1863 he invented the chilled shot (see Shell) that bears his name, and a system of strengthening cast-iron ordnance by the insertion of a steel tube. He retired in 1871, sat for Tavistock as M.P., and died 4th February 1882.

Pullium, the name given in the Roman Catholic Church to one of the ecclesiastical ornaments worn by the pope, by patriarchs, and by archbishops. It is worn by the pope at all times, as a symbol of his reputed universal and abiding jurisdiction. By archbishops it cannot be worn till it has been solemnly asked for and granted by the pope, and even then only during the solemn service of the great church festivals, and on occasions of the ordination of bishops or of priests, and other similar acts of his episcopal office. The pallium is made of a single band of white woollen web, about 3 inches wide, upon which black crosses are embroidered, which encircles the neck of the archbishop, and from which two narrow bands of the same material depend, one falling over the breast, the other over the back of the wearer. It is made wholly or in part from the wool of two lambs, which are blessed annually on the festival of St Agnes.

Palm (Paulina or Palmacea), a natural order of endogenous plants, the products of which are of extreme importance and utility to man. They are arborescent, with erect stems, usually slender as the exception, although the extension of the species attain, and simple or rarely branching; some are stemless, their leaves springing direct from the ground; others are succulents, twining about the stems and branches of neighbouring trees, by means of hooks or prickles, or trailing on the ground. The stems of almost all species are large and extreme slenderness, as in the case of many of the Call. Externally the stems are hard and bony, often coated with a siliceous deposit hard as flint, and finely polished; they are frequently armed with spines, and marked with the scars of dead leaves, or clothed in the upper part with the remains of the dead leaf-stalks enveloped in masses of fibre. The interior of the stem is generally soft and pithy, intermingled with handles of fibre longitudinally. So soft and easily extracted is the internal substance of the stems of many palms that the waterer may readily be turned into a cylindrical tube. The leaves vary much in form superficially, but all the variations belong to two types—the fan-veined and the pinnate-veined. In the former the general outline is that of a fan, with veins arising from the top of the leaf-stalk and radiating like the ribs of a fan. In the latter type the leaves are more or less elongated, with a distinct midrib extending to within a little of the extremity of the blade, which is always there cleft in two down to the point of the midrib, and with the veins springing from the sides of the midrib like the ribs of leaves; the last are sometimes entire, but more generally pinnate, and impart much elegance and grace to the figure of the particular species to which they belong. The size of palm-leaves varies extremely, some being only a few inches in length, as in some species of Malorix, while in Muscicapella suaveolens they attain the enormous proportions of 35 feet in length by 5 or 6 feet in breadth. The inflorescence is a simple or many-branched spadix enclosed in a spathe of one or several valves. The flowers are small individually, but numerous, usually of a yellow tint, and in some species powered with green; they are either unisexual, bisexual, or polygamous, the male and female flowers being borne in some species on different plants. The fruit when ripe is berry-like, drupeaceous, plum-like, or, as in the maca-nut, nut-like.

Palm are natives chiefly of the tropical regions of the earth. A few are found in extra-tropical countries extending to 36° N. lat. in America, 34° N. lat. in Asia, and in Europe Chamoprasus humilis, which is the only indigenous species, extends to 44° N. lat.; no species are found beyond 33° S. lat. Linnaeus, whose knowledge of palms was limited to the more arborescent species, very appropriately named them the 'Princes of the Vegetable Kingdom.' Their stately habit, the elegant proportions of the stems, and the graceful contour and outline with the leaves arranged over to the larger species, coupled with the great variety and utility of the products of all, mark them as most distinguished and valuable group of plants, gratifying the eye by their adornment of the landscape, and ministering abundantly to the necessities and the wants of human life.
and delicious vegetable. Many yield by incision or otherwise an abundance of sweet sap, from which sugar, refreshing drinks, wines, spirits, and vinegar are obtained. Their leaves are used for thatch, and for the making of mats, baskets, hats, umbrellas, thread, cord, and clothing. They yield excellent and inexhaustible materials, and they are in some cases a natural substitute for writing-paper, the records and writings of many eastern peoples being inscribed upon them.

The order comprises, according to Hooker and Bentham in Genera Plantarum, between 130 and 140 genera, and the number of species known is variously estimated by different authorities from 600 to 1000. The genus Chamaedorea is composed of about sixty species, all of slender, graceful habit, their smooth stems often not exceeding an inch in diameter, though they may be twenty or more feet high. They are used in South America for making bridges, as the bamboo is in China and India. The flowers of several of the species—including those of C. aurantiaca (fig. 1)—are highly esteemed as a culinary vegetable in some of the countries of Central America, but for this purpose they must be extracted from the spathe before it bursts. The fruit of Leopoldina major, called by the natives of Brazil Jara-sass, is collected by them and burned, and the ash, after being washed, is used as a substitute for salt. It is described, however, as being bitter rather than saline. Euterpe edulis—a native of Brazil—produces fruit in size, shape, and colour like that of the sbo. From the fruit of this species a beverage is made by infusion which is much relished. E. oleaceus produces an edible and nutritious cabbage. The Nibong of the Malay of the Eastern Archipelago is Oncosperma filamentosum, the cabbage of which is more highly esteemed than that of any other palm indigenous to that region. From the fruit of Euterpe betara a wholesome beverage called Palava-yakisé is made on the Rio Negro. The fruit of Oreodoxa regia, an extremely handsome palm, a native of Cuba, is too acid for human food, but is used there for fattening hogs.

Arecaceae is the Betel-nut Palm (see Arecaceae). The fruit enters into the masticatory of that name so much used in India. It contains gallie acid, much tannin, a principle analogous to catechum gunn, a volatile oil, a red insoluble matter, a fatty substance, and some salts. A spirit is obtained from it in two colours—one dark or black, which is extremely astringent; the other yellowish brown, which is less astringent and more pure. Besides being used as a masticatory and in medicine in cases of dysentery, the substance is employed in tanning leather and in dyestuffs. The terminal shoot of this palm furnishes an excellent cabbage, as also do several other species of Arecaceae. But the true Cabbage Palm in A. oleaceus, a noble species indigenous to the West Indies, attaining the height of 170 to 200 feet, with a diameter of stem of about 7 feet. The leaves are pinnate, about 20 feet long, the pinnules in full-sized leaves being often 3 feet in length. The terminal bud or cabbage is enclosed among many thin snow-white brittle flakes. It has the flavour of the almond, but with greater sweetness, and is boiled and eaten with meat. As its removal causes the death of the tree, it is regarded as an extravagant deficiency only rarely to be enjoyed, because of the great importance of the other products which the tree yields. The inflorescence is extracted from the spathes before they open, are pickled, and esteemed a delicate relish with meat. The nuts yield a useful oil by distillation. The shell or outer hard crust of the stem is employed in making gutters, and the pith yields a kind of sugar if extracted immediately the tree is felled; but if allowed to lie and decay on the ground, it becomes the brooding ground of a peculiar grub, which is greatly esteemed as a delicate article of food in Martinique and St. Domingo.

Ceroxylon (Triartic) andicola, a native of Peru, growing at an elevation of 8000-10,000 feet above sea-level, is a handsome species rising to the height of 160 or more feet. The stem exudes from the annular cicatrices of the fallen leaves a resinosous substance called by the inhabitants ceru de palma. It is composed of about two parts of a yellow resin and one part of wax, the texture of which is more brittle than beeswax. A sub-resinuous matter is also extracted from it named ceroxylon, which assumes the form of silky crystals, is soluble in alcohol, and phosphorescent by friction. The exudation, mixed with certain proportions of wax or tallow, is employed in candle-making. Besides the resins exudation the trunk yields a valuable and durable timber, the leaves are excellent and durable material for thatch, and they supply a strong, useful fibre for the manufacture of ropes and cordage.

The Kiziba Palm (C. exorrhiza) is a native of Central and South America, and is a singular and interesting tree on account of its peculiar habit of growth. The roots all spring from the stem above ground, every new root emerging from a point somewhat higher on the stem than the one which preceded it. And as the old roots decay as the new are produced and penetrate the ground, a tree of some age presents the curious spectacle of being supported on three or four legs long enough and wide enough apart to enable a man to pass between them erect. The timber is used in flooring and for making umbrellas-sticks, musical instruments, &c. Blowpipes (q.v.) for poisoned arrows are made from the stems of C. setigera.

The Sugar Palm (Arenga saccharifera, see fig. 2) is a native of the Moluccas, Cochin-China, and the Indian Archipelago, and is of immense value to the
of the stem, and by steaming the fruit after the natural exudation has been collected. The species are very numerous, about 200 having been described, but few are more singular than C. zeylanica (see fig. 4), a species which resembles a creeping or twining grass rather than a palm, the stems rarely exceeding in thickness stout wheat straw.—*Zalacca elulis* is regularly cultivated by the Burmese for the sake of its pleasantly acidulous fruit, which grows to the size of a walnut.

The sap from the exuding scaly pulv which encloses the seed is the edible part. — *Raphia* is the name of the edible or grateful fruit of Guinean palms, yields a rather abundant sap, from which a strongly spirituous wine is obtained. One of the most beautiful and singular of palms is *R. teodiara*, an inhabitant of the banks of the Amazon. The trunk of the tree is short, from 6 to 10 feet high, but from the sum in the long leaves arise almost perpendicularly to the height of 40 feet or more, arching gracefully outward towards the apex. The footstalk of these enormous leaves alone are often 12 or 15 feet long by 4 or 5 inches in diameter. The integument of these footstalks is thin, extremely hard and elastic, and light as a quill, and, being easily split into straight strips, is made into window-blinds, baskets, &c., by the Indians.

The true *sago* of commerce (see *Sago*) is derived from various species of the genus *Sago*, although other species of palm, as has already been stated, and also plants widely different botanically, such as *Cyos revoluta*, also yield a kind of sago. *S. cumphi*, *S. latifolia*, and *S. farinosa* are the species from which the largest quantity of true sago is obtained. *S. cumphi* is a native of the Indian Archipelago, Malacca, Borneo, Sumatra, Celebes, and the Moluccas being the principal places in which it is cultivated. The tree is small, rarely exceeding 30 feet in height of stem, which consists of a hard shell about 2 inches thick enclosing a mass of spongy pith—the sago. This pith is gradually absorbed after the tree reaches maturity, leaving the stem quite hollow. The proper time to fell the trees, before the pith begins to diminish in bulk or quality by absorption, is indicated by the upper leaves becoming covered with a sort of greyish or white dust. When felled the stem is cut into lengths of 6 or 7 feet, which are split, the better to remove the pith. There are various modes of extracting the feacula from the insoluble substances with which it is combined in the stem, but washing and straining are the principal methods of every process. A single tree, it is said, will yield from 500 to 600 lb. of sago.—The *Bacho* (*Macropia flexuosa*), a native of Guiana, supplies the chief wants of the people wherever it grows; the stems furnish timber for building their dwellings, the leaves thatch for the same, and material for mats, couches, hammocks, &c.; the pith yields sago; the juice by fermentation gives an excellent beverage; the kernels of

 natives of these countries on account of its various products. It yields an abundant sweet sap, from which a chocolate-coloured sugar named *jaggery* is made. The sap fermented makes an intoxicating drink variously named by the inhabitants of the different countries *neroo* or *brown*. From the pith of the stem *sago* is obtained, in great quantity, a single stem yielding as much as from 150 to 200 lb. The leaves supply *Gossano fibre*, which is celebrated for its great strength and durability when formed into cordage and ropes, and at the base of the leaves a fine spongy material, named *bora*, is developed in mature trees, which is employed in canoeing ships, stuffing cushions, and making timber.

Caryota urens (see fig. 3), one of the noblest palms of India, yields some remarkable products. The flesh of the fruit, which resembles a plump in size and structure, is very acid, and corrodes and burns the lips and mouth. From the terminal bud a sweet watery liquor is obtained, which, when boiled, yields *jaggery*. The terminal bud is also eaten as a cabbage. From the pith of the stem *sago* is obtained, which is made into bread, and prepared in various other ways, and is a valuable article of food for the natives. The tree is named *Kittel* in Singhalese, and the fibre called *Kittel*, obtained from its leaves, is most valuable to brushmakers (see FIBROUS SUBSTANCES).

The genus Calamus and its immediate allies are regarded as forming a connecting link between the palms and the grasses, having the inflorescence and fruit of the former and in some cases the habit of the latter. Certain species—viz. *C. Roxburghii*, *C. Bogaleana*, both of which are included in *C. rotang* by some authors, and *C. siminicus* and others—furnish the rattan canes employed in making ropes and cables, chair bottoms, couches, baskets, mats, &c. The walking-sticks known as Malacca canes are made from the stems of *C. sepium*, a species which grows not in Malacca, but in Sumatra, and the canes are chiefly exported from Siam in that island. The stems of the Great Rattan (*C. rufescens*) and others are of prodigious length, extending to hundreds of feet, clinging by hooks attached to their leaves to the trunks and boughs of neighbouring trees, or trailing on the ground. They are extremely hard externally, and usually smooth, with a dense sili-}

Fig. 3.—Caryota urens.

![Palm Tree](image-url)
fruit are ground into meal and made into bread; and the fibre is converted into cordage and clothing.—The Palmyra Palm (Borassus flabelliformis) is one of the most common of its tribe in India. In some parts of the country it grows spontaneously, and in others it is cultivated. It is about 30 ft. in height, and it is the subject of careful cultivation. It furnishes the greater part of the palm-wine of India, which by the natives and Fanusis is called Calvii and Noongapo, and by Europeans Toddy. The fruit is about the size of a child's head, somewhat triangular, and within it is a thick, brown, oily juice containing three seeds about the size of a goose's egg. The seeds when young are eaten by the natives, being jelly-like and palatable. The toddy is obtained by wounding the spathes before the inflorescence expands. After a few days a clear, sweet liquor exudes from the wound, and is carefully collected in pots suspended under the wounded spathe. A tree yields about three quarts daily. The liquor is drunk fresh, and will only keep sweet for about three days, when it undergoes fermentation and becomes sour, and is distilled into toddy. Juggerly is also made from the juice. The young plants when a few inches high are cooked and eaten as a vegetable. The leaves, which are fan-shaped and large, are turned to the various uses alluded to in connection with species already described, and in India they are extensively used for writing upon with an iron stylus.

The Double Cocoa-nut, or Sea Cocoa-nut as it has been called, is Lodoicea seychellitana. The nuts of this tree are seen occasionally in museums and in the cabinets of collectors of curios, often beautifully polished and carved by native workmen, and formed into caskets and other ornaments. For long their origin was shrouded in mystery. They were frequently found floating about in the ocean before the discovery of the tree, and an absurd belief was entertained by Malay and Chinese sailors that they were the fruit of some marine tree. The tree, a native of the Seychelles Islands, is very elegant, attaining a height of from 50 to 80 feet, with leaves 20 feet long supported on stalks of equal length. The fruit is one of the largest produced by any of the palms, being a foot or a foot and half in length. The kernel near the base is divided into two parts—hence the name Double Cocoa-nut—and while young part of the fleshy substance in which it is enclosed is edible. The chief products of the tree are timber and fibre for cordage, and a downy kind of fibre, which enables it to be used for filling mattresses and pillows. The Talipat Palm of Ceylon (Corypha umbraculifora) is not only for the variety of uses to which its leaves are put in Ceylon and other parts of India to which it is indigenous. The leaves are of immense size, and being palatable with the leaf-stalk attached near the middle, they are readily formed into umbrellas and tents; the cane-like ribs being removed and the blades neatly stitched together, they may be folded up with great facility. They are used by the natives to make clogs called colatha of the inhabitants. Many of these alleged to be made of Egyptian papyrus are formed of the leaves of this palm. The tree grows to the height of 100 feet, and has a very grand and imposing appearance. A closely allied species (C. taliera) is the Talipat Palm of the Moluccas. The tree grows to about the same height as the preceding species, with leaves of a more durable kind for the purposes of thatch, but not so adaptable to more delicate and artistic uses.—Livistoa petlata is the Chittah-pat of Assam, the leaves of which are extensively used for making umbrellas, punkals, and hats. The stems of L. antifeolia are made into walking-sticks, named by Europeans Penang Lawyers. —Coperния cierifera, a native of northern Brazil, produces an edible fruit; and from the leaves, after they have been removed from the trees and dried, is obtained an inferior kind of vegetable wax, which is used in candle-making and to adulterate beeswax.

Of the American Palmetto Palm, a native of the Carolinas and Florida, the most important species is the Cabbage Palmetto (Sabal palmetto), which sometimes grows to 50 feet in height and 15 inches in diameter, with leaves 5 feet long and broad. It is found also in the Bermudas. Its products are timber and the leaves, the former being exceedingly durable, very porous (see Moultrie), and especially valuable for wharf-building, as it resists water and is not attacked by the teredo. The fruit is not edible.—The Palmetto of Europe is Chamaerops humilis, which inhabits the countries on both shores of the Mediterranean, occupying great tracts. It rarely reaches 10 feet in height, and usually is much less, its growth being exceedingly slow. The leaves are fan-shaped and abundantly in excellent fibre, with which the Arabs, combining it with canes and hair, make tent-covers; in Spain it is made into ropes and sailcloth, and in France it is made into carpets, named African haircloth. The French in Algeria make paper and pasteboard of it, and so well adapted is it to this purpose that its use might be more extended in other countries. They are also extensively used by the Arabs and the inhabitants of Sicily and Southern Italy. The plant endures the climate of London, but scarcely grows. C. Ritchiana, a native of Sind and Afghanistan, and C. celerula, a native of China and Japan, both produce excellent fibre. The leaves of Thrinax argentina supply the material called clap, of which ladies' hats and bonnets of that name are made. The trunks of T. purpurea, a native of Jamaica, though of slender diameter, are said to be very suitable for pilons and marine buildings subject to immersion, as they are impervious to the influence of water, and are not attacked by borers or worms. Sabal (Sabal palmitae) mautitiformis, a native of New Grenada (fig. 5), is a low-growing but very hardy plant not remarkable for any product of special utility.

The Piritu of Venezuela, the Paripoun of Guyana, and the Peopão of the Amazons are the local names of one species of palm—Gualibana speciosa. It produces fruits somewhat triangular in shape, about the size of an apricot, and bright reddish yellow in colour. They have a peculiar oily flavour, and are eaten boiled or roasted, when they resemble chestnuts. They are also ground into meal, which

Fig. 5.—Sabal (Trinatax) mauritiformis.
PALMA

PALM

is baked in cakes.—The Great Macaw tree of the West Indies (Acrocomia vitorubra) is a native of Jamaica, Trinidad, and the West Indian Islands, and is called Munuahua, and in Guiana Macoya. The tree grows from 20 to 30 feet high, with a crown of leaves, each of which measures from 10 to 15 feet in length. The fruit yields an oil of yellow colour, sweetish taste, and having the odour of violets, which is employed by the natives for an emollient for painful afflictions of the joints; and in Europe it is used in the manufacture of toilet soaps. The nuts are capable of receiving a high polish, and are converted by the natives and the negroes into ornaments.—The Tucum Palm (Astronium guianense) is native of the Rio Negro and the Upper Amazon, yields a very superior fibre, the cullage from which is knitted into hammocks, which are in great demand with the Brazilians. The fleshy outer covering of the fruit is eaten by the natives.—The Marunuru Palm (A. marunum) produces a very agreeable fruit with the fragrance of musk. Cattle eat the fruit with avidity, but evacuate the hard stony seeds undigested. In times of scarcity these seeds are carefully collected and used to feed pigs, which are very fond of them, and find no difficulty with their powerful teeth and jaws in overcoming the shells. —The fruit of A. ferox furnishes the whalebone-like fibre now so much used in Britain for making brooms and brushes. The tree attains the height of 20 or 30 feet. At the base of the leaves a valuable thick, dark-brown, very long fibre, Banana bark, some 12 feet long, Para or Monkey bast, a softer, shorter kind, usually about 3 feet in length, is got from Leopoldina pianissima (see Fibrous Substances). The fruit of Attalea funifera is the Coquilla nut, much used in turnery for the making of knives and pens. A small bunch of seeds, called bell-pulls, &c. The nuts are extremely hard and susceptible of a fine polish, and exhibit a beautifully mottled surface of light and dark brown.—The fruit of A. columnae yields from its kernel a valuable oil called Columbia Oil, which is said to be superior in quality and to burn twice as long as the best cocoa-nut oil. It is a native of Honduras and the Isthmus of Panama. The trunk, which attains the height of about 40 feet and is crowned with leaves some 30 feet long, yields a tapping of a kind of palm wine. —The Palm oil of Africa is a product of the fruit of Elaeis guineensis. The tree is cultivated now in the West Indies and tropical South America for the sake of the oil. It attains a height of 60 to 80 feet, with a spreading crown of pinnate leaves, each about 15 feet long, the footstalks of which are armed with stout hooked spines. The flowers have a strong peculiar smell, like amase and chervil in combination. The fruit forms a large head, consisting of a great number of bright orange-coloured drupes; when ripe each drupe has an oily pulp with a stone in the centre. It is from this pulp that the oil is obtained. To extract the oil the pulp is first bruised to a paste in wooden mortars, and is then boiled in water. The oil which rises to the surface of the water is reddish or orange in colour, and has an agreeable odour of violets and arums. It is then skimmed off. In warm countries it retains its oily consistence, but in cooler climates it acquires the solidity of butter. It is used by the natives universally as butter in Europe. The quantity of palm-oil now imported to Great Britain is enormous. It is employed for the manufacture of various perfumery and toilet articles, common soaps, and as a lubricant of railway carriage wheels, &c. It is composed of about thirty-one parts of stearin and sixty-nine of olein. The tree yields from its trunk abundance of palm-wine.—The Coquito of Chili is Jubaera spectabilis, a tree of about 50 feet in height, with a spreading crown of large brown leaves. The sap is extracted, called miel de palma, which is much esteemed by the Chilians and Europeans in cookery in various ways. It is obtained by cutting down the tree and lopping off its crown of leaves, when the sap flows from the wound, and is collected by cutting off a fresh slice from the wound daily, or when the flow of sap becomes weak, it may be kept flowing for several months; a good tree is said to yield as much as ninety gallons of sap, which on being boiled down assumes the consistency of treacle.

Much information on palms and their products will be found in the Historiae Palmarum, by Martius; in the Flora Brasiliensis, by Drude; and A Popular History of Palms, by Seemann. See ARECA, COCOA-NUT, CHAMBEROPS, DATE PALM, DOOM PALM, FIBROUS SUBSTANCES, &c.

Palm, a measure of length, originally taken from the width of the hand, measured across the joints of the four fingers. In Britain a palm is, somewhat loosely, understood to be the fourth part of an English foot, or 3 inches.

Palm, JOHANN PHILIPP, a bookseller of Nuremberg, who has acquired historic celebrity as a victim of Napoleon tyranny. In 1800, at the age of 36, he was sent by his firm to a bookseller in Augsburg in the ordinary course of trade. The book fell into the hands of Napoleon's officers; they made the emperor acquainted with it. He ordered Palm, as the publisher, to be arrested, tried him by court-martial, and shot him at Brauns, 26th August 1806. This murder greatly incensed the German people against the French.

Palma, (1) the capital of the island of Majorca (q.v.) and of the Balearic Islands, stands on the bay of Palma, on the south coast. The cathedral, a Gothic edifice (1232-1601), contains the tomb of King Jaime II. of Aragon and a valuable collection of church ornaments. The tomb of Raymond d'Aguilar, in the church of St. Mary, are, further, a beautiful exchange (1420-40), an old Moorish palace, and a 16th-century town-hall, with pictures. Palma is one of the most aristocratic cities in Europe. Pop. (1887) 90,514. They weave silks and woollens, make jewellery, and various articles of common use. The port is protected by a mole, and the town by a wall and batteries. The commerce reaches a total value of about £1,600,000 per annum.—(2) A town of Sicily, 14 miles SE. of Siracusa. Pop. 11,792.—(3) The name of one of the larger of the Canary Islands (q.v.).

Palm, JACOPO, commonly called PALMA VECCHIO (i.e. Old Palma), painter of the Venetian school, was born about 1480 at Serimeta, near Bergamo, and died at Venice just about the middle of the year 1528. At first working under the influence of the Bellinis, he subsequently, in the spirit and style of Tiziano, acquired a great reputation. Palma, Titian, and may be placed at the head of the second class of great Venetian artists. His pictures are either sacred subjects or portrait groups. Of the former the best are a series of figures of saints, St Barbara and others, in the church of St Maria Formosa. Of the portrait group this is three sisters, generally called the 'Three Graces.'—His brother's grandson, likewise called JACOPO (1534-1628), and nicknamed IL GIOVANE (the Younger), painted religious pictures of greatly
inferior merit, though he modelled his style on that of Titian, Palma Vecchio, and Tintoretto. Except for eight years in Rome, he spent all his life in Venice.

Palmerston. See CASTOR-OIL PLANT.

Palma Christi. See CASTOR-OIL PLANT.

Palmer Adelphi, Vilhelm Frederik, a Swedish historian, was born 16th December 1788, at Lii-
jested, in East Gotland, where his father held a post under the government, studied at Upsala, and became professor of Greek in the same university in 1833. He died 21 September 1852. Amongst his works (which were returning home after the fulfilment of his vow. The Palms were so called from their carrying branches of the oriental palm, in token of their accomplished expedition. On arriving at their home they repaired to the church to return thanks to God and offered the palm to the priest, to be placed upon its altar.

Palmer, Edward Henry, the 'Sheikh Abdul-
lah,' was born 7th August 1840, at Cambridge, and while a schoolboy there picked up Romany (the Gypsies' tongue), while a clerk in the City Italian and French. In 1839 he all but died of consumption; in 1840 at Cambridge began to devote himself to oriental studies—Arabic, Persian, and Hindustani; in 1863 obtained a saship at St John's; and in 1867, graduating with a third-class in classics, was yet elected a Fellow of his college. During 1868-70 he was engaged for the Palestine Exploration Fund in the survey of Sinai, and, with Charles Tyrwhitt Drake, of the Desert of the Wanderings, acquiring meanwhile a marvellous knowledge of the wild Arab tribes. In 1871 he was appointed Lord Almoner's professor of Arabic at Cambridge (his stipend £40, 1s., augmented next year by £200); and in 1874 he was also called to the bar. So ten years went by of work and play—he was a wonderful conjurer—of sorrow, too, and trouble, for he lost his first wife and got involved in money difficulties, till in 1881 he turned London journalist, was appointed special correspondent to the St. Petersburg Gazette. Finally, in June 1892, on the eve of Arabi's Egyptian rebellion, he was pitched on by government for the perilous mission of winning over the Sinai tribes to Britain and hindering the destruction of the Suez Canal. He made two expeditions—the first his great ride from Gaza to Suez (July 15-31), and the second when, starting from Suez with Captain Gill, R.E., and Lieutenant Charrington, R.N., he and they on August 11 were betrayed and murdered in the ravine of Wady Sudr. Eight months later the three were buried in St Paul's.

Palmer. By the baronet. Palmer may be men-
ioned his Desert of the Exodus (1871), Arabic Grammar (1874), Song of the Reed (1876), Poems of Behâd il Din Zohair (1876-77), Persian-English and English-Persian Dictionary (1875-83), Haroon Arasped (1880), and a translation of the Koran (1880). See his Life by W. Besant (1883).

Palmer, Roundell. See SELBORNE (LORD).

Palmerston. Henry John Temple, Vis-
count, was born at the manor house, Broad-
lands, near Romsey, Hants, 29th October 1784, and belonged to the Irish branch of the ancient English family of Temple, taking name from Temple in Leicestershire. Sir W. Temple, the diplomatist and patron of Swift, was a member of this family,
he resumed the seals of the Foreign Office. His second foreign administration furnished various subjects of hostile party criticism, among which may be mentioned the civil war in Switzerland, the Spanish marriages (see GUISO), the European revolutions in 1830, and the numerous diplomatic relations between Spain and Great Britain, and finally, the affair of Don Pacifico (a Gibraltarian Jew living in Athens, who claimed the privileges of a British subject), and the consequent quarrel with Greece. His strenuous self-asserting character, his brusque speech, and the intemperate language with which his political enemies, foreign and domestic, were little calculated to conciliate opponents at home, and secured him many enemies abroad—the name 'Firebrand Palmerston' still clinging to him on the Continent. A vote of censure on the foreign policy of the government was in 1836 carried in the House of Lords on the motion of Lord Stanley (afterwards Earl of Derby). A counter-resolution, approving the foreign policy of the government, was thereupon moved by Mr. Roebuck in the Lower House. The debate lasted four nights. In a speech of five hours' duration—then called the 'Roebuck speech'—which neither caused us all so proud of him—Palmerston entered upon a manly and dignified vindication of his foreign policy; and Mr. Roebuck's motion was carried by a majority of forty-six. In December 1831 the public were startled at the news that Palmerston was no longer a member of the Russell cabinet. He had expressed to the French ambassador in London his approbation of the coup d'état of Louis Napoleon, without consulting either the premier or the Queen; and, as explanations were refused, Lord John Russell placed his resignation in the hands of Palmerston, in the general opinion, was 'smashed'; but he soon got his 'tit for tat;' for in the following February, soon after the meeting of parliament, he avenged himself by shattering the Russell administration to pieces on a comparatively trifling question—a Militia Bill. He refused an offer from the Earl of Derby to join the government which he was commissioned to form, but accepted the post of Home Secretary in the condition administration of the Earl of Abercorn in 1832. The fall of this coalition government in the winter of 1834-35, on Mr. Peel's motion for a new ministry, placed Palmerston in his seventy-first year in the position of prime-minister, to which he was unanimously called by the voice of the nation; in his own phrase he was 'the inevitable.' He vigorously prosecuted the Russian war until Sebastopol was taken, and peace was made on terms which defeated in March 1857 on Mr. Cobden's motion condemnatory of the Chinese war. Palmerston appealed to the country, and met the House of Commons with a largely increased majority. But his administration fell in February 1858, over the Conspiracy Bill, intended to protect the French emperor against the machinations of plotting refugees. A short Conservative administration followed; but in June 1859 Palmerston was again called to the post of First Lord of the Treasury, which he held till his death, the chief events of this premiership being the American civil war (with its Trent and Alabama incidents), Napoleon's war with Austria, and the Austro-Russian war with Denmark. His last great speech was his defence of the policy of his government. On 7 July 1861, he died of Mr. Disraeli. He died at his country seat, Brockwell Hall, 18th October 1865, and was buried in Westminster Abbey. Both his titles became extinct with him.

It was his ambition to be considered the minister of the nation rather than the minister of a political party; and his opponents have been constrained to admit that he held office with more general acceptance than any English minister since the time of the great Lord Chatham. As an orator he was usually homely and unpertaining, but always sensible and practical. He was a dexterous speaker, always able to play a ready, witty, and often brilliant debater. He was popular as a minister, because he was thoroughly English in his ends and aims. Even his robust health, off-hand manner, manly and usual jument bearing, and physical vigour were elements of his popularity, because they were regarded as a glorification of the English sports, which he was never ashamed to patronise. He desired nothing so ardently as to promote the prosperity, influence, and grandeur of Great Britain, and his national character and national spirit were thoroughly appreciated by his countrymen.

See Life of Palmerston, by Lord Dalling (2 vols, 1870), continued by Evelyn Ashley (2 vols, 1879); and smaller works by Anthony Trollope (1882), Lloyd Sanders (1888), and the Marquis of Lorne (1891).

Palmerston (Australia). See PORT DARWIN.

Palmer-worm, a name given to many large kinds of grub, the larve of coleopterous insects, destructive to various vegetable substances.

Palmetto-leaves, the leaves of the Palmyra palm (see PALM, p. 723), imported into Europe for the manufacture of hats and mats. For the palm known as Palmetto, see PALM, p. 729.

Palmieri, Luigi, meteorologist, born 23 April 1807, taught mathematics, became in 1847 professor at Naples, and in 1854 director of the observatory on Vesuvius. He invented many meteorological instruments, and wrote on volcanoes and seismology. He died 6th September 1866.

Palmipedes, also called NATATORES, or SWIMMERS. A well-footed and some classifications an order of birds. See Bird.

Palmistry, or CHIROLOGY (Gr. cheir, 'the hand, and manitiké, 'divination'), is the art of 'reading the palm'—the art which professes to discover the temperament and character of any one, as well as the past and future events of his life, from an examination of the palm of his hand, and the lines traced upon it. As a considerable body of very complicated rules and directions have been laid down by authorities, ancient and modern, to enable the student to read the palm, palmistry claims to be regarded as a 'science,' or at least as a branch of an interpretative science of the hand in general, to which the name Chirology has been given. The other branch of this general science has been called chiromancy, and is concerned with the interpretation of the form and character of the hand and fingers, while Chiromancy treats of the palm only (see DIVINATION).

As an art palmistry appears to be of great antiquity. Mr. Neshied, in his Report on the caste system in the North-west Provinces and Oudh (1885), tells us that there is a caste of Brahmins, called Joshi, who profess the art of fortune-telling by means of marks on the palms of the hands, the face, and the body generally; and who seem to have practised it from remote times. Palmistry has an ancient literature of its own in India; the ancient Sanskriti appears to have had some acquaintance with letters, but the Joshi, his modern counterpart to the art, is quite illiterate, though he generally carries about with him a manual of palmistry, of whose contents he knows nothing. There are also a number of wandering castes in India who tell fortunes by palmistry.

That palmistry was to some extent at least known to the ancient Greeks we have evidence in the writings of the Stagirite himself. In his
Hist. Animalium Aristotle observes (i. 15) that long-lived persons have one or two lines which extend through the whole hand; short-lived persons have two lines not extending through the whole hand. Other references to this subject occur in the doubtful works, the Problemati and the Physiognomika, attributed to him. Pliny, too, in Natura Animalium (xi. 114) directly asserts that Aristotle regarded numerous broken lines in the palm of the hand as a diagnostic of short life.

Of the cultivation of palmistry among the Romans there is little evidence; but Juvenal, in showing up the curiosity of women and their love of prying into forbidden mysteries, describes the woman of fashion as consulting eagerly Chaldean astrologers and other diviners, while the middle-class woman 'frontemque manumque praelibat vati' (Sat. vi. 581). In the 2d century Artemidorus of Ephesus, the author of a work on the interpretation of dreams, is said to have devised a whole treatise to the subject, which, however, is not extant.

In writers of the middle ages there is much reference to the subject, and the names of Pargaeus, Albertus Magnus, and Castalans have been associated with it. But the most important work on chiroiomy belonging to this period seems to be Die Kunst Chironomantia, of Johann Hartlieb, which was printed at Augsburg in 1475. In the 16th century we find several treatises on the subject, of which the most important seem to be those of Johann Ingehagen and of Barbier and Coesee 'De Bonlaigne,' doctor of natural philosophy and of medicine. The former has been Englished by Fabin Wither (London, 1651). In the end of the 16th century palimistry found an important exponent in the celebrated Marie Anne Lenormand (1722-1845), whose her Souvenirs Prophéte de D'Un Sublime (1814) foretold the downfall of Napoleon.

The chief authorities on palmistry in recent times are two Frenchmen—M. le Capitaine D'Arpentiny and M. Adrien Desbarrolles; and it is on their work that modern English books on the subject are chiefly founded. D'Arpentiny has expounded principally chiroiomy, or that branch of the interpretative science of the hand which treats of the general form of the hand and fingers. The observation of the fingers and joints of the hand—called Jupiter and the chiroiomy of that of the palm itself—but we must refer for D'Arpentiny's system to the works cited below. The thumb is generally regarded as chiroiomyically the most important part of the hand. The first, or upper phalange of the thumb, when well developed, shows the presence of will and decision of character; the second, according to its development, indicates more or less logical power (see A and B in diagram). What has to be considered by the chiromant proper is the 'mounts' of the hand, with the marks on them, and the lines in the palm. The 'mounts' or elevations are the base of the fingers and thumb and in the 'perception' of the hand—i.e. the side of the palm which extends from the root of the little finger to the wrist—is so called because it is used in striking. They are seven in number, and are marked from the inner to the outer planets—e.g. Jupiter denotes pride and ambition; Saturn, the elements; Mars, courage and energy; Venus, love and melody; the Moon, folly or imagination.

The effect of a greatly developed mount may be modified by the lines in the palm or by other signs. There are four principal lines—viz. the line of life, which surrounds the thumb, and which, if long, indicates a long life; the line of head, the line of heart, and the russette or the bracelets. These last (the bracelets), if well marked, strengthen the effect of the line of life, each bracelet indicating thirty years of life. The line of heart (the linea manudis of ancient chiroiomy), if long, clear cut, and well coloured, denotes an affectionate and devoted character; and the nearer the line stretches to Jupiter the better the character. If the line end in a fork, so much the better. In actors and orresses this line ascends the mount of Mercury.

A good line of head—i.e. a clear-cut, long, unbroken line—indicates the presence of superior intellectual qualities. If the line stretch to the mount of the Moon, it indicates imagination. A winding head-line shows folly and indecision of character; a linked line (like a chain) denotes want of concentration. The other lines (which are not present in all hands) are the line of Saturn or fate (d, d), the line of Apollo (f, f), the line of Venus or love (c, c), and the line of Venus (g, g). A long, clear-cut line of Saturn (see diagram) foretells a happy and prosperous life; Proper windings in the line foretell misfortunes or obstacles; a good line of Apollo shows that its owner will be successful in art; a good life-line promises a long and healthy life; while the Venus line (Cingulum Veneris), when marked, indicates a character very liable to be influenced by the passion of love. Marks on the mounts or lines, such as stars, crosses, &c., have their respective significations. A good open space between the lines of head and (the quadrangle) indicates a generous and noble disposition, while a very narrow space in the quadrangle is a sign of avarice and egotism.

The best handbooks are D'Arpentiny, La Chiroiomy (Paris, 1845); A. Desbarrolles, Les Mysteres de la Main (1859); and his Evolution des Coudes (1874); Beamp, The Psychology of the Hand (1862); A. H. Craig, The Book of the Hand (1867); H. Frith and E. Heron Allen, Chiromancy, or the Science of Palmistry (1883); Heron
Palm Sunday. See PALM, and OILS.

Palm-tree. See PALM.

Palmyra, in ancient times, from about 100 A.D. to the 14th century, more especially in the 2d and 3d centuries, a wealthy and magnificent Arabian settlement, planted at a spot that formed a convenient station on the great caravan route between the Persian Gulf and the Mediterranean. At all events, after the decline of Petra (q.v.; also NABATAEANS) in 105 A.D., Palmyra took its place as the chief commercial centre in northern Arabia. Its merchant aristocracy reaped great advantage from the long-protracted wars between Rome and Parthia. An enormous length of gigli over the supremacy of Rome. From both Hadrian and Septimius Severus it received special favours and privileges. One of its chiefs, Odenathus, husband of the more famous Zenobia (q.v.), extended his power over most of the adjoining countries, from Egypt to Assyria Minor. An attempt was made in 272 the attempt of the Palmyrenes to found an independent empire. After the Roman empire became Christian Palmyra was made a bishopric. When the Moslems conquered Syria Palmyra also submitted to them. From the 15th century it began to sink into decay, along with the rest of the Orient. Magnificent remains of the ancient city still exist, chief among them being the great temple of the Sun (or Baal); the great colonnade, nearly a mile long, and consisting originally of some 1500 Corinthian columns; and sepulchral towers, overlooking a part of the city. The ancient Palmyra besides conducting and controlling the caravan trade across the desert, extracted salt, tanned leather, and worked in gold and silver.

See Wood, Bonner, and Dawkins, Ruins of Palmyra (1788); Schaf, Reisen in der Asiatischen Türkei (1785); a Russian work by Prince Abamelek-Lassereff (1833); and Dr W. Wright, Palmyra and Zenobia (1856).

Palmyra Wood. properly the wood of the Palmyra palm (see PALM, p 729); but the name is generally used for all kinds of palm-tree wood imported into Britain; much of which is the wood of the coconut palm, Cocos nucifera, and the allied species C. hummzum.

Palni Hills, a range of Southern India, linking the southern extremities of the Eastern and Western Ghats; average height of the higher ridge, 7000 feet. The climate of the Palni Hills is singularly pleasant and equable, many preferring the sanctuary of Kodaikanal to Ootacamund.

Palo Alto, 33 miles S.E. of San Francisco, the seat of a university founded at a cost of $15,000,000 by Senator Leland Stanford, and opened in 1891. It is designed to provide, entirely gratis, education from the Kindergarten stage to the most advanced instruction that human teachers can supply; the pupils are to board on the premises, at the smallest possible charge. Pop. (1900) 1038.

Palolo (Palolo viridissima), an edible annelid, allied to the Lug-worm, extremely abundant at certain seasons in the sea above and near the coral-reefs which surround many of the Polynesian Islands. The body is cylindrical, slightly tapering at both ends, divided into nearly equal joints, each small tube with legs on each side. In thickness the palolo resembles a very fine straw; in length it varies from 9 to 18 inches. These annelids make their appearance in great multitudes, apparently rising out of the coral-reefs, and with a periodical regularity which is very remarkable. They are eagerly sought after by the islanders, who are on the watch for their appearance, and go out in canoes before sunrise to take them by means of nets; but they often occur in such

PORTICO OF THE GREAT COLOMNAE

City of northern Syria, situated in an oasis on the northern edge of the Arabian desert, about 150 miles N.E. of Damascus and nearly midway between that city and the Euphrates. The Scnittic name was Tadmor, Palmyra (= "city of palms") being the Greek and Latin equivalent. According to the old tradition, it was founded by Solomon. There is stronger probability that it was an
numbers that the water seems to be full of them, and they may be grasped by handfuls. After sur-
rise the creatures break into pieces and the shoals are not seen till the next period, which seems to last for a definite duration to the lunar time; the two stated periods being in October and again in November.

**Palos**, a small Span-
ish port at the mouth of the Rio Tinto, and 5
miles S. of Huelva. Once an important place, from whence Columbus started on his great voy-
age, it has now sunk to a village of 1200 inhabitants.

**Palpitation** is the term used of the condi-
tion in which a person becomes painfully aware of the beating of his own heart. This occasionally happens even when the heart’s movements appear clearly and apparently quite natural; but much more generally the pulsations are found to be greatly increased in
force, and in most cases in frequency as well. It may be either functional or a symptom of organic disease of the heart. Here we shall merely consider it as a functional disorder. Although it may be persistent, it far more frequently comes on in
paroxysms, which usually terminate within half an hour, recurring afterwards quite irregularly, sometimes daily or several times a day, and some-
times not till after a long interval. The attack often comes on under some mental or physical excitement, but sometimes when the patient is quite composed, or even asleep. If the paroxysm is a severe one the heart feels as if bounding up-
wards into the throat; and there is a sensation of oppression over the cardiac region, with or without difficult respiration. Excluding organic diseases, the causes of this affection are either (1) an
abnormally excitatory condition of the nerves of the heart, or (2) an unhealthy condition of the blood.

(1) Amongst the causes that may give rise to
paroxysms in a patient suffering from palpitation, is the abuse of tea (especially green tea), coffee, spirits, and tobacco. Any irrita-
tion of the stomach and intestinal canal may be re-
lected to the heart; and hence palpitation may
frequently be traced to flatulence, undue acid-
ity, and intestinal worms, especially tapeworms. Everything that causes pressure on the heart, such as tight-lacing, abdominal dropy, or an enlarged uterus, is also likely to occasion this affection.

(2) If the blood is abnormally rich and stimulating it may give rise to palpitation, as in Pethorn (q.v.); but the opposite condition, known as
Anaemia (q.v.), is a much more common cause of
this affection. In anaemia the blood is watery and deficient in fibrine, and (far more) in red colour-
ing matter; and, being thus in an unnatural state, it acts as an unnatural stimulus and produces fre-
quent and abnormally strong pulsations.

The age at which palpitation most usually comes
on is from fifteen to twenty-five; and the affection — especially if it arise from anaemia — is very much
more common in the female than in the male sex.

The treatment of palpitation may be very much de-

depended upon its cause. The use of all nervous stimulants (tea, coffee, alcohol, and tobacco) should be sus-
pended or abandoned. If the patient is clearly
plethoric, with a full strong pulse, he should take
saline cathartics, and live upon comparatively low
diet (including little animal food) until this condi-
tion is removed. When, on the other hand, the
palpitation is due to an anemic condition, the
remedies are preparations of iron, aloeetic purgatives, and an abundance of animal food, bitter ale, the cold
shower-bath, and moderate exercise.

**Palsy**. See **Paralysis**.

**Palstock, Robert**, born in London apparently
in 1697, and educated at St Paul’s School, was
bred to the law, and while in Clement’s Inn secured his title to remembrance by writing the
wondrous tale of Peter Wilkins, a Cornish Man,
published anonymously in 1750, and often re-
printed. The authorship, known to some in 1802,
remained generally a mystery till 1835, and first
appeared on the title-page in 1839. Palstock died
20th March 1767. See the preface to A. H.
Bullen’s edition of Peter Wilkins (2 vols. 1884),
and Athenaeum, August 1884 to February 1885.

**Paludan-Müller, Frederik**, Danish poet,
born at Kjerteminde in Fünen, on 7th February
1809, led a quiet, uneventful life, and died at Copenhagen on 29th December 1876. Whilst still a student at the university in that city he gained the ear of the Danish Academy with his play Juno (1832); a poem, The Pome (1833); and a lyric drama, **Amor and Psyche** (1834; 8th ed. 1883)—all three decidedly romantic in temper, the second especially showing Byronic influence. But his fame rests on **Adam Homo** (3 vols. 1841–49; 7th ed. 1886), a luminous didactic poem, full of
depth and suggestive thought, with no small share of satiric wit and irony, and strong realistic touches,
and of the most finished literary workmanship; on
**Kalanusa** (1854), a contrast between Alexander the Great and the Indian sage Kalanusa, as representa-
tives of Greek culture and Hindu religion, a work
written in the loftiest spirit of idealism; and on
**Adonis** (1874), an exquisitely finished little mytho-
logical poem. Along with **Kalanusa** he published the poems **Paradise, Abel’s Death, Cain, Ahasuerus, and Benevolence of Kings**; and he wrote 1881 two
prose romances, The **Source of Youth** (1865) and
**Fruh Lypcke’s History** (3 vols. 1866–73). His poetic
works were published in 8 vols. in 1878–79. See
**Georg Brandes, Danske Digtere** (1877).

**Pamir** (‘roof of the world’), the name of the
central Asian highland system, is a lofty plateau-region extending from the Tien Shan chain of moun-
tains, extending the western terminations of the
Himalaya and the Tien-Shan Mountains, and both with the
Hindu-Kush. It is traversed by mountain-ridges that rise from 4000 to 5000 feet above the
plateaus, and the culminating points attain in some cases 25,500 feet above sea-level. Between these ridges are a series of broad valleys, to which the generic
name ‘pamir’ is given. On the west side this
plateau-region sinks rapidly in terraces to the
deserts of Turkestan. These lofty plateaus are exposed to great extremes of heat and cold, and are
visited by terrible snow and sand storms. Nevertheless the Kirghiz drive up their flocks and
herds for summer pasture, and from time immem-
orial traders have crossed them along celebrated
routes. It is traversed by Marco Polo (q.v.),
Animal and Bird life is little developed in the
mountain having its home there. Amongst the lakes are
Karakul, 120 sq. m., and Shakaluk, 100 sq. m. See
the Earl of Dunmore, The **Pamirs** (1893); Alocock’s
**Report of the Boundary Commission** (1888); Sven
Hedin’s **The Pamirs** (1898).

**Pamlico Sound**, a shallow body of
water, some 75 by 10 to 25 miles, on the coast of North Carolina, separated from the ocean by long, narrow
islands of sand, with narrow passages.
Pampas (Quêchua, ‘plains’) is a term properly confined to the immense treeless plains of the Argentine Republic, which rise, almost imperceptibly, in a series of terraces from the coast to the base of the Cordilleras. Extending some 2000 by 300 miles, they differ greatly in various districts. The north-easterly portion, in the Paraná basin, is one of the most fertile regions in the republic; and stretching from this through Buenos Ayres and the south of Cordova and Santa Fé is the rich grayly pampa-land proper, supporting great herds of cattle, horses, and sheep. The rest is for the most part waterless and sterile. The soil, which is a diluvium composed of sandy clay, and abounds in the bones of extinct mammals, is more or less impregnated with salt, especially in the west, where strips of desert, known as tierras, are numerous. Within recent years great tracts of pasture have been converted into farm-land, but stock-raising is still the most important industry. The half-wild herdsmen are called Ganches (q.v.).—The name Pampas is also given to the level districts of Peru, where those of the Sacramento occupy an area estimated at 180,000 sq. m., covered with pine-wood forest.

Pampas Grass (Cynodon argenteus), a grass which covers the pampas of South America. A noble grass now well known in British gardens as an ornamental plant, it is quite hardy, and its tufts have a splendid appearance. The leaves are 6 or 8 feet long, the ends arching gracefully over; the flowering stems 10 to 14 feet high; the panicles of flowers silvery white, and from 18 inches to 2 feet long. The male and female flowers are on separate plants; the spikelets two-flowered, one floret stalked, and the other sessile; the panicle of the female florets elongated, awn-shaped, and woolly. The herbage is too coarse to be of value. The plant is now cultivated at Goleta, California, for the sake of its panicles, which are vended by florists for room decoration. Their culture and preparation for market form a considerable industry.—Another species of the same genus, G. melehnurus, a Brazilian grass, yields a considerable quantity of sugar.—A decoction of the root of G. pareiflorum is used in Brazil to strengthen the hair.

Pampas hare. See Viscacha.

Pampelona, or PAMPIOLA, a fortified city of northern Spain, stands on a tributary of the Ebro, 111 miles by rail N.W. of Zaragoza (Saragossa) and 56 S. by W. of Bayonne in France. It has a citadel (a copy of that of Antwerp), a Gothic cathe-

dral (1367), a viceregal palace, a fine aqueduct, a natural history collection, a college of surgery, and a bull-ring, manufactures of pottery, leather, cloth, and distillery, &c., and a trade in wine. It was visited by the ancients Pompygopolis, because built by Pompey in 68 B.C. It was taken by the Goths in 466, by the Franks in 542, and by Charlemagne in 778. From 907 it was the capital of Navarre. It was occupied by the French in 1521 that Loyola (q.v.) received his wound. The town was regained by the French in 1808, and held by them till 1813, when it was captured by Wellington. It again capitulated to the French in 1823. In the Carlist wars it was held by Queen Christina’s adherents from 1836 to 1854, and several times attacked several times by the Carlists. Pop. 25,030.

Pamphlet. The word is used by Hoccleve in 1411, who applies the name ‘pamflet’ to his rather long poem De Regimine Principum, and by Caxton, who spells it ‘pamflet.’ Beyond this we know nothing for certain—the ultimate origin may be Pamphilus, the name of a first-century writer of epitomes. In the 15th century the word was applied chiefly to short poems, and the modern meaning was only gradually assumed. Davies (1715) in his Icon Libellorum, or Critical History of Pamphlets, defines it as ‘any little book or small tract, or pamphlet... whether good or bad, whether serious or ludicrous, whether esteemed or slighted.’ It is evident, however, that some literary characteristics must be added in order to exclude sermons, academic dissertations, chap-books, brochures, &c. The pamphlet has a distinct aim, it relates to some matter of current interest, religious, political, or literary, and, whether didactic, religious, or controversial, is the spontaneous expression of one who seeks to excite or change some popular feeling or opinion. In England the history of pamphlets would be the history of the thought of the people. From the tracts of Wycliffe and his followers in the 14th century to the Tracts for the Times in the 19th, from the heights of noble enthusiasm in Milton’s Areopagitica and Tract on Education to the most scurrilous of party pamphlets, all reflect, or capsule, some phase of popular opinion. Perhaps of the earliest and most effective of such appeals to the public precipitated the course of ecclesiastical events in the 16th century—i.e. the Supplication for the Beggars, in which Simon Fish (1523) sharply satirised the ‘bishops, abbots, priors, monks, seculars, and other inhabitants of the clergy of this country.’ This was sent to Anne Boleyn, and ‘divers copies scattered in the streets of London.’ To this Sir Thomas More replied with his Supplication of Souls. Then followed an increasing flow of Puritan pamphlets, and in 1587 the famous Martin Marprelate series commenced, and in 1657 the Killing no Murder attracted more attention than any other political writing of the time. The enormous collection of publications, chiefly pamphlets, made by Thomas the bookseller, now in the British Museum, running merely from 1640 to 1692, yet filling 2000 volumes, tells the history of the Civil War from day to day. The Pamphleteer, 1813–28, in twenty-nine volumes, contains the best pamphlets of that period, and is full of material for history. In our day the multitude of quarterly reviews, monthly magazines, and weekly papers gives to authorship a certain amount of circulation; yet the pamphlet reappears whenever popular feeling is really aroused, or in the propagation of such causes as anti-vivisection, anti-vaccination, and the like. Some prolific topics have been the Ballot Question (1870), the New Laws (1893), the Canadian Revolt (1877–79), the Corn Laws (1841–48), the Crimean War and the Indian
PAMPHYLIA

Panamy, anciently a country on the south coast of Asia Minor, with Cilicia on the east and Lydia on the west. It was originally bounded on the inland or northern side by Mount Taurus, but afterwards enlarged, as to reach the confines of Phrygia. Pamphyliab was formerly well wooded, and had numerous maritime cities. The inhabitants—a mixed race of aborigines, Cilicians, and Greek colonists—spoke a language the basis of which probably was Greek, but which was disfigured and corrupted by barbaric elements. See Dr. Leneckowski, Die Stadte Pamphyliens und Pamiliens (1820 et seq.).

Pan, among the Greeks, a divinity of pastures, forests, and flocks, usually described as a son of Hermes. His worship originated in Arcadia, but spread gradually over the rest of Greece, although it did not reach Athens until after Marathon. Pan is represented as having horns of Amadon's head, a crooked nose, pointed ears, a tail, and goat's feet. Sometimes he appeared to travellers, startling them with sudden fear, whence a sudden fright was called a paniek fear. During the heat of the day he used to sleep, and the sun passing over him excitedly wroth if his slumber was disturbed by the hallow of the hunters. He was the patron of all persons occupied in the care of cattle and of bees, in hunting and in fishing. He is also represented as fond of music, and of dancing with the forests nymphs, and is the inventor of the oboe or Panolian pipes. Cows, goats, lambs, milk, honey, and new wine were offered to him. The first tree was sacred to him, and he had sanctuaries and temples in various parts of Arcadia, at Trezene, at Sicyon, at Athens, &c. The Romans identified the Greek Pan with their own god Faunus. Plutarch (De Orac. Defect.) is the first to tell the story that in the reign of Tiberius one Thamus a pilot, when steering near the islands of Patre, was commanded by a loud voice to proclaim that the great Pan is dead. As soon as he had reached Palodes he cried the news of his death. And when the poem was repeated upon was heard a great noise of lamentation, as of nature itself expressing its grief. The coincidence of this story with the birth or the crucifixion of Christ gave occasion to an explanation that it suited the world. And as the old world began to decline and the new was beginning of the new when the old oracles became dumb, Rabalais has the story, there is a well-known allusion to it in Milton's Ode on the Nativity, and it has been finely treated by Schiller and Mrs. Browning. The Devil of popular Christian superstition owes some of his attributes to Pan.

Panamá, Isthmus of, formerly called the Isthmus of Darien (q.v.), embraces the narrow part (35 miles) of Central America, connecting Costa Rica on the W. with Colombia on the E. It now forms a part of Colombia, has an area of 31,850 sq. m., and a pop. of 285,000, with 8000 unchristianized Indians, and is traversed by a low chain of mountains, forming the barrier between the Atlantic and Pacific Oceans. Numerous streams, the largest of which is the Tuir (100 miles long, and navigable for more than 100 miles), fall into both oceans. Off the Pacific shore are numerous islets of the group of the Tuitas and Perlas, so called from their pearl-fishery (now almost discontinued), Naos, and Tabaga are the chief. There are no good natural harbours. The chief trading ports are Panamá (see below) and Colon (Aspinwall). The exports embrace hides, tallow, cauchos, indigo, vanilla, coffee, gold dust, cocoa-nuts, tortoiseshell, &c. Commerce is entirely in the hands of foreigners, and is valued at less than $1,000,000 annually. Gold, once abundant, is still worked, and copper, iron, and bauxite exist. 'Panamá hats' are made in Ecuador and Peru.

Panamá, the capital of the department, stands on a projecting volcanic rock on the Pacific side of the Isthmus; the massive walls the Spaniards built to protect their stevedores from the rain. Old Panamá, founded in 1518, was captured and destroyed by the buccaneers under Morgan (1671). Modern Panamá was built two years later, 4½ miles distant from the old city. In May 1888 it had a population estimated at 15,000, the majority of whom were negroes and people of mixed breeds. During the zenith of canal work (see below) the population was estimated at 25,000 to 30,000. Fires have destroyed Panamá repeatedly, as well as its sister city Colon. The principal buildings are the cathedral (1780), a Spanish structure, the bishop's palace (1880).

Panamá Canal.—The idea of connecting the Atlantic and Pacific Oceans by way of the central American isthmuses is by no means new. That for uniting them by the Isthmus of Panamá is almost coincident with Balbi's discovery of the canals (1510-20), and King's claim to the founding of the isthmus, and we read: 'In the town library of Nuremberg is preserved a globe, made by John Schoner in 1520. It is remarkable that the passage through the Isthmus of Darien, so much sought after in later times, is on this globe carefully traced.' Gomara (1510-60), the historian, was the first to hint the idea of a union of the oceans by means of a canal. Philip II. of Spain proved an implacable enemy to all such schemes. The Telumantepec, Nicaicara, and Darien routes were discussed in the 16th century; and the Dutch, it is alleged, made complete plans for a canal across two centuries ago. But no steps were taken to carry out any plan until Ferdinand de Lesseps, of Senez fame, convened in Paris in May 1879 an international congress to discuss the plan of cutting through the Isthmus of Panamá. A plan previously made by De Lesseps was adopted, and a concession from the United States of Colombia to Lieutenant Lucien Napoleon Bonaparte Wyse of the French navy, who had made a lusty and partial survey, was sold to the prospective Panamá Canal Company. On February 28, 1881, the first detachment of canal employed arrived at Colon; surveys were at once made, and the building of camps, hospitals, &c., followed. In 1882 the Canal Company purchased the Panama Railway. De Lesseps' Engineering Commission to Panama in 1880 recommended that a canal could be made for $33,000,000 francs, De Lesseps reduced their figures to 600,000,000 francs, or $24,000,000, and announced that a canal 4 niveau, or tide-level canal, could be completed for that sum. Later he invited delegates to meet him at Panamá in 1888 for its opening. Loans followed year after year. Meanwhile interest charges accumulated and became burdensome, while little real progress was made. In the autumn of 1888 further borrowing became impossible. The company was forced into liquidation, January 1, 1889; its bond and share indebtedness was roughly estimated at $270,000,000, interest charges over $4,000,000, with perhaps a fifth of the real work done. There are over 800,000 holders of shares in France. Shortly after the crash, a Liquidation was named by the Court of the Seine. In 1890 a commission of French and other engineers was sent to the Isthmus by him. Their report was very discouraging. Valuable
plant estimated at about £6,000,000 was rusting away, much already useless. The tide-level cut at Colon was rapidly filling in, and the fine harbour the Frenchists are in the cut in. In 1893 the government of Colombia granted to the Panama Canal Company an extension of ten years from 1883 in which to finish their contract; provided operations should be resumed before February 1893. De Lesseps seems to have entered upon the plan without solving the kind of tide-level cut. The Frenchists alleged that much money was squandered through extravagance and incapacity. Moreover, many hundreds of the workmen were swept away by tropical diseases, yellow and pernicious fevers, dysentery, &c., the efficacy of the Ishmus being pestilental and death-dealing. Indeed the Ishmus and its towns are hotbeds of malignant disease, distributed thence by passing merchandise to all quarters.

The obstacles to a tide-level canal are great; such as the swamps and volcanic ledges on the Panamá side; and the marshes and quicksands on the Atlantic coast are apparently insurmountable. The periodical overflow of the Chagres fills the valley of the Ishmus, as in the flood of 1879, which swept all before it, and covered the railway with 12 feet of water. The wet season of nearly eight months causes inundations to occur. Earthquakes, too, occur, as in September 1882, which did much damage to both Ishmus cities and the Panamá Railway, whilst a tidal wave caused great destruction of life and property on the islands and coast of the Gulf of Darien; and to natural obstacles must be added that of labor in the valley. See Nelson, *Five Years at Panama* (N. Y. 1889; Lond. 1891).

**Panama Crimson.** See DYEEING.

Panathenaic, the most famous festival of Attica, celebrated at Athens in honour of Athena, patron goddess of the city. All writers who mention it speak of a Lesser and Greater Panathenaic, the former annual, the latter quadrennial. The procession of the festival was sculptured by Phidias and his disciples on the frieze of the Parthenon.

**Panax.** See GINSENG.

Panay, an island of the Philippines (q. v.), south of Luzon. Ares, 4,540 sq. m. Mountain-chains run parallel to the east and west coasts. It is exceedingly fertile, and has vast pastures. Capiz, Hiloio, and Panay (pop. 15,484) are the chief towns.

Panels, the oldest extant collection of apologues and stories in Sanskrit literature. This work is a compilation due to a Brahman named Vishmwarman, who is represented as at once the narrator of the stories and author of the book. Composed of narratives, some of which are found in different literary monuments, and of passages borrowed from legislators, moralists, and poets, the *Panchatantra* has been subjected to many modifications. Wilson, who first gave a detailed analysis of the work (Trans. Roy. Asiatic Soc. of Great Britain, 1, Lond. 1827), has said what is really applicable to Benfrey, the first editor of the Sanskrit text, found the same variety in the eleven MSS. he used. In these he recognised two distinct redactions, one simple and without ornament, the other more extended and elaborate. Neither of these, however, is, the first form of the work. Benfrey held that there existed a still more ancient text, from which the lost Pehlevi translation was made, and that the *Panchatantra* was composed subsequent to that translation. This Pehlevi version was the parent of the Arabic *Kutla'ih w<;<; Dimmah* (Nippur) of the ninth century, and of the old Syriac versions of Stickel and Breci (1879). The best of these is the book of *Kuttah w<;<; Dinnah* which differs considerably from the *Panchatantra*. It is divided into eighteen chapters, of which only five (5, 7, 8, 9, 10) correspond to the five parts of our collection. The literary history of this work and its extraordinary diffusion among the languages of western Europe are sketched in the article INDIAN.

*Some* of the fables contained in the *Panchatantra* are found in the Mahābhārata, others have their source in Buddhist books, and there exist in Sanskrit several abridgments or imitations. Of these the most ancient forms part of the Kathasaritsagara (see the *Stories of Story*), composed by Somadēva about the beginning of the 12th century. The text of this work was edited by H. Bruckhaus (Leip. 1839-62-66); a German translation by the same scholar was published in 1839 (Leip. 2 vols.), and one in English by Professor C. Tawney (two vols., Lond., 1889). It contains, of the Panchatantra, the first three books, three fables of the fourth, and one of the fifth. Another abridgment, in which most of the poetical quotations are omitted, is entitled *Kathārántasyādhi* ("Treasure of the Ambrosia of Stories").

The most celebrated of its imitations is the *Hitapadās* ("Useful Instructioon"), of comparatively modern date. Like Somadēva, its author, Śrī Nārāyana, has taken only the first three books of the Indian original; he has drawn from the last two four fables only, and inserted them in his third and fourth books.

The *Panchatantra* belongs to the class of works designated in India as *Nicādātās (veda, 'book of knowledge,' and *niti, 'conduct'),* composed for the instruction of princes and all those called to take a share in the direction of public affairs. The five books of which it is composed form as many distinct parts, related to each other by an introduction in which a king, after having taken the advice of his councillors, entrusts to a Brahman the education of his three sons. The latter composes the *Panchatantra* for the instruction of the young princes, and by the reading of those fables he succeeds in overcoming their indolence and in developing their faculties.

The first book is the longest, and has for special title *Mitrabheda* ("The Disunion of Friends"). Its object is to acquaint kings how dangerous it is to lend an ear to the pernicious insinuations of those who seek to sow divisions between a prince and his faithful friends. The second book, entitled *Mitratipāti* ("The Acquisition of Friends"), has for its aim to show how advantageous it is to form unions and help each other. The third book, *Rākalokikni* ("The Voice of the Croes and the Owls"), shows the danger of trusting to men unknown or to enemies. The fourth, *Lalbharpanasana* ("The Loss of Acquired Goods"), proves that we often lose by imprudence what we had gained with difficulty. The fifth and last book, *Aparicchakakāvya* ("Inconsiderate Conduct"), shows the danger of being too precipitate in action. A principal apologue forms the subject, or, more correctly, the introduction, of each of the five books. Fables contained in that apologue, and often involved the one with the other, are related by the personages introduced. The narrative is written in a mixture of sentences, maxims, remarkable thoughts, extracts from codes of legislators, heroic and other poems, and dramas.

The text of the *Panchatantra* has been edited by Koser (2 vols. Bonn and Greifswald, 1845-60), and G. Bühler, who was born in the Low Countries in 1806, and died in 1869. There is an admirable German translation by Benfrey (2 vols. Leip. 1850), a French translation, with useful notes on the sources and imitations of the stories, by Henri Lacombe (2 vols., Paris, 1865). This work is entirely taken up by a masterly and exhaustive introduction, the best work that has yet appeared on the sources and the diffusion of Indian fables.

Pancras, St., the son of a heathen noble of Srumada in Phrygia, lost both parents whilst a
Pancreas

(Pancreas) is a glandular organ in the abdomen that produces digestive enzymes and hormones. It is situated near the stomach and liver. The pancreas plays a crucial role in digestion by secreting enzymes that help break down fats, proteins, and carbohydrates in the small intestine. Hormones produced by the pancreas, such as insulin and glucagon, regulate blood sugar levels.

Pandurs

Pandurs are a family of birds known for their large size and distinctive calling sound. They are often found in forests and grasslands and are known for their social behavior. Pandurs are sometimes used in traditional hunting practices in certain cultures.

Pandora

In Greek mythology, Pandora was the first woman on earth. She was created by the gods as a gift to mankind, but contamination came with her gift of knowledge. Her brother, the Titan Prometheus, had stolen fire from the gods and gave it to mankind in a box. When Pandora opened the box, all the evils of the world—pain, suffering, and disease—escaped. Only hope was left inside the box, serving as a reminder of the inevitable presence of hope in the face of adversity.
PANDULF

The people they defended as to the enemy, and about 1750 they were put under stricter discipline, and gradually incorporated with the regular army. The name is now obsolete.

Pandulf, Cardinal, the commissioner sent by Innocent III. to King John in 1213, who returned to England as legate (1218-21), and in 1219 a Bishop of Norwich, Langton strongly opposed his pretensions as legate, and got his commission cancelled.

Panorama

Pangæan Lingua (Lat. "Now, my Tongue, the mystery telling"), one of the most remarkable of the hymns of the Roman Breviary, and like its kindred hymn, Lumen Sion, a most characteristic example of medieval Latin versification. The Pangæan Lingua is a hymn in honour of the eucharist, and belongs to the service of the Festival of Corpus Christi. It was written by the great Anglic Doctor, Thomas Aquinas, and consists of six strophes of verses in alternate rhyme. Besides its place in the office of the Breviary, the 'Tantum ergo,' a portion of this hymn, forms part of the service called Benediction with the Blessed Sacrament, and is sung on all occasions of the exposition, procession, and other public acts of eucharistic worship.

Pangollin, or Scaly Ant-Eater, a name given to the various species of the genus Manis belonging to the mammalian order Edentata, and confined to the Oriental and Ethiopian regions. The most marked peculiarity of these animals is their covering of scale-like structures, which are really formed of numerous hairs closely fused. The pangolin is most nearly allied to the Aardvark (q. v.) of South Africa, and like it is edentate and feeds upon ants. When threatened with danger these animals roll themselves into a ball like the hedgehog.

Pangæa. See Samoa.

Panic. See Grasses.

Panicum. See Millet.

Pānini, the greatest known grammarian of ancient India, whose work, equally admirable for precision of statement and analytical skill, has up to the present day remained the standard of Sanskrit (q. v.) grammar. Of his life little is known save that he was born near Atoke, in the 7th century A.C., according to Goldstücker, while Weber and Bödlink give about 230 B.C.

Panipat, a town of the Punjab, is situated 53 miles N. of Delhi, near the old bank of the Jumna, and on the great military road of northern India between Afghanistan and the Punjab. Hence it has been at various times the scene of strife between the peoples of India and her invaders. The first great battle of Panipat was fought in 1526, when Baber, at the head of 12,000 Mongols, defeated the army, 100,000 strong, of the emperor of Delhi. The second great battle was fought in 1556 by the Mongols under Akbar, grandson of Baber, and third of the Mogul emperors, against Henn, an Indian general of the Afghan Sher Shah, the latter being defeated. The third battle was fought on 7th January 1761 between Ahmed, ruler of Afghanistan, and the till then invincible Mahrattas, who on this occasion suffered a total defeat and great slaughter. The existing town is enclosed by an old wall, and manufactures copper utensils, cloth, blankets, hardware, silver and glass ornaments. P. (1891) 27,574.

Panizzl, Sir Anthony, principal librarian of the British Museum from 1821 to 1891, and a member of the University of Oxford from 1828 to 1891. When the University of Oxford was transferred from Oxford to the town of Oxford, Sir Anthony became a lecturer in the University and was made a member of the University Senate. His researches in the field of the printed books of the 18th and 19th centuries led to the publication of several works on the subject, and his name is associated with the establishment of a library and museum for the University of Oxford.

Panjáb, a province of India. See Punjab.

Panjām, a city of Portuguese India. See Goa.

Panónia, a province of the ancient Roman empire, bounded on the N. and E. by the Danube, on the W. by the mountains of Noricum, and on the S. reaching a little way across the Save; it thus included part of modern Hungary, Slavonia, parts of Bosnia, of Croatia, and of Carniola, Styria, and Lower Austria. It received its name from the Panonians, a race of doubtful origin, but who at first dwelt in the country between the Dalmatian Mountains and the Save, in modern Bosnia, and afterwards more to the south-east in Musia. The Roman arms were first turned against them and their neighbours, the Iapides, by Augustus in 52 B.C. The Panonians defeated Julius Caesar, who settled about 8 A.D. in the more northern countries, which received their name, and of which the former inhabitants, the Celtic Boii, had been in great part destroyed by Caesar's time. The country was now formed into a Roman province. Great numbers of the Panonians went southward as the Roman legions. In the 5th century it was transferred from the Western to the Eastern Empire, and afterwards given up to the Huns. After Attila's death, in 453, the Ostrogoths obtained possession of it. The Longobards under Alboin made themselves masters of it in 567, and relinquished it to the Avari upon commencing their expedition to Italy. Slavonian tribes also settled in the south. Charlemagne brought it under his sceptre. In the reigns of his successors the Slavonians spread northward, and also for a series of painted pictures, such as what is called "the Panorama of the Rhine," folded up in a kind of portfolio. The name is also given to a continuous series of painted pictures exhibited at one end of a room, and moved so as successively to pass into and out of the field of view by some mechanical arrangement. This when seen from a distance
through an opening, and under a combination of direct and reflected light (as invented by Daguerre and Boutron), is called a diorama. But the word panorama properly belongs to what is now called, by way of distinction, cycloorama—a continuous painting on the interior of a cylindrical surface, the spectator standing in the centre. It is claimed that Breising of Danzig proposed such a plan. But Robert Barker (1759-1806), an Irish painter resident in Edinburgh, is entitled to the credit of having conceived the method, but of having successfully carried it out on a large scale; his first 'panorama' being a view of Edinburgh, painted in water-colour on paper pasted on a cylinder of canvas 25 feet in diameter, and exhibited in Edinburgh in 1798. This he took to London in 1799; and in 1803 he erected a special building, one of the rooms of which admitted a circular picture 90 feet in diameter. Robert Fulton is said to have painted and exhibited shortly after this the first panoramas seen in Paris. But on the Continent the panorama in this sense first became very popular after the Franco-German war of 1870-71. In various towns of Germany and in Paris panoramas of the war were exhibited in buildings specially built for the purpose; the Parisian one of the siege of Paris being enormously successful. In the United States also large panoramas have been exhibited, the subjects being battle-scenes from the civil war. A large panorama of the battle of Kormokpur, painted by Fleischer of Munich, was shown in a specially erected building in Glasgow in 1884; and one of the battle of Tours, painted by the same artist, was a feature of the Edinburgh Exhibition of 1890. In the same year Niagara was brought on canvas to London, and in 1891 this was succeeded by a view of Jerusalem on the day of the Crucifixion. Cycorama is the name given to a delineation of the earth's surface on the interior of a hollow sphere, the spectator being in the centre of the whole (see Globes).

Panormus. See Palermo.

Panstavism, a movement with the aim of drawing closer together all the various races of Slavonic stock, and combining their influence in political and other directions. Some extreme Slavophils have even proposed an actual amalgamation in nationality, language, literature, and religion. The majority representation was won in 1870 by the Slav poet Kollár (q.v.), and the movement showed first in Bohemia (q.v.), where the philosophical and historical work of Schafarik and Palacký contributed to give it impetus. The Poles of Prussia resisted Germanisation; Serbs, Slovaks, and Croats asserted their rights against their Magyar masters; and the still less fortunate Slavs of Turkey gladly swallowed the chorns. But at the first great Panstavistic congress at Prague in 1848 the most convenient medium of intercourse proved to be the tongue of the alien Germans! Russia, after being asked to suppress the Hungarian agitation, came to be regarded as the protector of all Slavs; and the papers and periodicals of Russian Slavophiles, such as Aksakoff and Katkoff, heartily promoted this growing feeling. The growing dominion of Russia caused to suppress the Hungarian revolution, and came to be regarded as the protector of all Slavs; and the papers and periodicals of Russian Slavophiles, such as Aksakoff and Katkoff, heartily promoted this growing feeling. The growing dominion of Russia caused to suppress the Hungarian revolution, and became in the end the protector of all Slavs; and the papers and periodicals of Russian Slavophiles, such as Aksakoff and Katkoff, heartily promoted this growing feeling. The growing dominion of Russia caused to suppress the Hungarian revolution, and became the protector of all Slavs. The Austrian Slavs felt themselves put into the background by the reconstitution of the Austro-Hungarian monarchy in 1867, which gave so much more power to the Magyars. The war in the Balkan Peninsula in 1875-78 was doubtless largely due to Panstavist intrigue as well as to Christian grievance, and the arrangements that hence taken effect since the Berlin treaty, especially the resolute self-assertion of the Bulgarians, have somewhat disillusioned Russian Panstavists. See Slavs; Russia; and Hauer, Der Panstasmus (Berlin, 1886 et seq.).

Pansy. See Violet.

Pantagraph, or PANTOGRAPH (Gr. pant, 'all'; graphein, 'to delineate'), an instrument invented for the purpose of making copies, reduced or enlarged, of drawings or plans. It is made in various forms, one of which is shown in the figure. Four rods are so hinged to one another that AE is equal to DF, and AD to EF; hence ADFE is always a parallélogram. If from a given point C on AE any straight line BH (or a, b) be drawn, putting the other arms, the triangle ABC will always, no matter how the arms of the instrument be moved, be equal to the triangle DHI. It follows that, if the instrument be pivoted on a point at B (usually by a weight), a pencil-point inserted at A and a tracing-point at C, and the latter traced over the lines of a drawing, the pencil-point at H will trace a reduced copy of the drawing. The proportion of the reduction will be that BH is to BC, and H and A are made to slide on their respective rods, so that any proportion of reduction can be made. By changing the places of the pencil and tracing-point, an enlarged copy may be made. The instrument is fitted with little castors to facilitate its free motion. The pantagraph was invented by the Jesuit Christoph Scheiner prior to 1631, and improved by Professor W. Wallace of Edinburgh prior to 1831.

Enlargements or reductions can now be done so much more accurately by means of photography that the pantagraph is nearly obsolete. See Copying.

Pantellaria, a volcanic island in the Mediterranean, 30 miles in circumference, and lying 60 miles SW. of the Sicilian coast. In the chief town (Pantellaria, pop. 3600) is a great convict prison.

Panthalos. See Chiru.

Panthays, a Mohammedan community occupying the province of Yunnan in the south-west of China, who asserted their independence in 1855. In 1859 they captured Tafileh, the second city of the province, and in 1858 the capital. Their leader Wun-soo (King Sulaiman) established his authority over about 4,000,000 of people, of whom not above a tenth were Mohammedans. In 1860 the Chinese government, finding the independence of the Panthays, and in 1872 their king sent his son Hassan on a mission to Europe. Meanwhile the Chinese again attacked the Panthays, defeated them utterly, and finally suppressed their empire. Panthays is
PANTHEISM

PANTOGRAPH

an Anglicized form of Pan-the, their own name. They are still numerous.

Panthemism (Gr. pan, 'all,' and theos, 'God'), the name given to that system of speculation which, in its spiritual form, identifies the universe with God (akosmeism), and, in its more material form, God with the universe. It is only the latter kind of pantheism that is logically open to the accusation of relativity; the former has often been the expression of a profound religion. The word Pantheism is comparatively modern, and seems to have been coined by the Deist John Toland in 1705, and is used shortly after that date by his opponents, the orthodox writers like Waterland. Earlier pantheistic systems, such as Spinoza's, were regularly assailed under the name of atheism. But the antiquity of this mode of belief is undoubtedly great; it is prevalent in one of the oldest known civilisations in the world—the Hindu. Though it may dinly underlie certain pantheistic systems, it is obviously in any definite shape a later development of thought than polytheism, and most probably originated in the attempt to divest the popular system of its grossest features, and to give it a form that would satisfy the requirements of philosophical speculation. Hindu pantheism, the Hindu pantheon as akosmeism is taught especially by the Upanishads, the Vedanta and Yoga philosophies, and by those poetical works which embody the doctrines of these systems; for instance, the Bhagavad Gita, which follows the Yoga doctrine. It is poetical and religious, rather than scientific, at least in its phraseology; but it is substantially similar to the more logical forms developed in Europe. The Hindu thinker regards man as born into a world of illusions and entanglements, from which his great aim should be to deliver himself. Neither sense nor reason, however, is capable of helping him; only through long continued, rigorous, and holy contemplation of the supreme deity (Brahma) can he become emancipated from the deceptive influence of phenomena, and fit to apprehend that he and they are alike but transmuted modes of existence, infinite, eternal, and unchangeable Spirit who is all in all. Hindu pantheism is thus spiritual in its character; matter and (finite) mind are both alike absorbed in the fathomless abyss of illimitable and absolute being. Buddhism (q.v.) denies or ignores the existence of God, but in many modes of regarding the universe is rather akin to pantheism than to absolute atheism. Sufism is a pantheist outgrowth of Islam.

Greek pantheism, though it doubtless originated in the same way as that of India, is at once more varied in its form, and more rationalistic in its method of exposition. The philosophy of Anaximander may be described as a system of atheistic physics or of materialistic pantheism. Xenophanes, the founder of the Eleatic School (q.v.), has been held to be the first classical thinker who pronounced the hypothesis of a pantheistic God. Alexandrian Neoplatonism is substantially pantheistic; the universal reason and the world-soul of medieval thinkers have the same tendency. The Mosaic account of the Creation (q.v.) of all things out of nothing by God expressly excludes any pantheist connotation; and Christian cosmologists strenuously assert against every form of pantheism that it involves an antichristian theory of the origin of Evil (q.v.), subverts the personality of God and man, renders free will impossible (see Will), and destroys all real moral responsibility. Many philosophers have become Gnostics, Gnosticism is based on an essentially pantheistic doctrine of emanation. Dionysius (q.v.) the Areopagite and Scotus Erigena (q.v.) were pantheists within the Christian fold; and the later Christian Mysticism (q.v.) has a highly pantheistic flavour (see ECKHART, BOHEME). Bruno, Vanini, and Parmeinus were outspoken pantheists; and there were various minor pantheistic sects in the middle ages. Spinoza is perhaps the greatest, certainly the most rigorous and precise of the whole class that either the ancient or the modern world has seen. Schelling's Nature-Philosophy proposed to limit the meaning of the term pantheism to the doctrine of the immanence of all things in God, but leaving doubtful the precise scope of what was meant by immanence; and some forms of Hegelianism are directly pantheistic in character. Neither England, France, nor America has produced a single great pantheistic philosopher; but there is an immense amount of pantheistic sentiment floating about in the poetry, criticism, theology, and even in the speculative thinking of these and all European countries in the present age.

See the articles on the thinkers mentioned, and those on PHILOSOPHY, RELIGION, and THEISM; the works on Pantheism by Jüscbe (1826-32) DiBüner (1851) Weissenborn (1859), and Driesen (1894); Swiet., Modern Pantheism (Eng. trans. 1853); Fellenius, Le Panthéisme (1873); Flint, Pantheism and Christianitie (1866; 2d ed. 1884) Flint, Anti-Thomist Theories (1877); Plumptre, History of Pantheism (2 vols. 1881).

Panthem (Gr. pantheon), a temple built in a modified Corinthian style with a great vaulted roof, dedicated to all the gods. The 'Pantheon'

Half-section of Pantheon (from Ferguson).
**PANTOMIME**

Pantomime, among the ancient Romans, denoted not a spectacle but a person. The pantomimoi were a class of actors who acted wholly by mimicry in gesture, movements, and posturings, corresponding therefore pretty closely to the modern ballet-dancers. When they first made their appearance in Rome cannot be ascertained; probably the *katria* or *Etruscan dancer* brought from Etruria to Rome 364 B.C. were pantomimes; but the name does not once occur during the republic, though it is common enough from the very dawn of the empire. Augustus showed great favour to this class of performers, and consequently supported some writers who had been himself the inventor of the art of dumb acting. The most celebrated pantomimes of the Augustan age were Bathyllus (a freedman of Mecenas), Pylades, and Hylias. The class soon spread over all Italy and the provinces, and became so popular with the Romans, that writers and critics that Tibullus reckoned it necessary to administer a check to their vanity, by issuing a decree forbidding the aristocracy to frequent their houses, or to be seen walking with them in the streets. Under Caligula they were again received into the Metamy and attributed unworthy weakness and vice to the extremity of caricature, himself acted as a pantomime. From this period they enjoyed uninterrupted popularity as long as paganism held sway in the empire. As the pantomimes wore masks, no facial mimicry was possible: everything depended on the movements of the body. It was the hands and fingers chiefly that spoke; hence the expressions, *manus loguacissima, digitii eloquenti,* &c. To such perfection was this art carried that it is said the pantomimoi could, in a few minutes, produce the most exquisite emotion to passion and action than the poets themselves. The subjects thus represented in dumb show were always mythological, and consequently pretty well known to the spectators. The dress of the actors was made to reveal, not to conceal, the beauties of their person; and as, after the 2d century, women began to appear in public as pantomimes, the effect, as may easily be supposed, of their costume, or lack of costume, was prejudicial to morality. Hence pantomimic exhibitions were denounced by the early Christian writers, as they were even by pagan moralists like Juvenal.

The pastoral drama in medieval Italy gave birth to the opera, and already in the 16th century we find on the Spanish stage ballads with dramatic figures and the first was introduced. But the improvised Italian comedy was already familiarly known far beyond Italy, with its conventional comic figures, Pantonone and Arlecchino. In England the mask and so-called opera of the 17th century supplied the place of the modern pantomime, and which grew out of an attempt to reproduce a popular light dramatic entertainment, varied with song and dance, itself the parent of the modern French *vaudeville.* Colley Cibber mentions as the first example a piece on the *Loves of Mars and Venus* which he gives the year 1725, when the commencement of pantomime in England, with *Harlequin Dr Fannyus* by John Thurmond, presented at Drury Lane. John Rich (1681-1781) produced splendid pantomimes at Lincoln's Inn Fields and Covent Garden, and that flair for the mimetic entertainment became a traditional institution.

In the older English pantomimes the harlequin played a serious as well as merely comic part; cymbeline (originally his daughter) was a village maiden whose lover was pursued and finally constrained—the prototypes of the modern policemen. The predominance of the clown seems to be a modern development, mainly due to the exceptional ability of Joseph Grimaldi. Now the chief reliance of the manager is on scenic and spectacular effects, large sums of money being lavished on the mise en scène.

**Papa** (Lat., 'father'), the Latin form of the title now, in the Western Church, given exclusively to the Bishop of Rome (see *Pope*). Originally, however, meaning simply 'father,' it was given indiscriminately to all bishops. In the Greek Church, whether in Greece Proper in Russia, *papa* is the common appellation of the clergy.

**Papacy.** See *Pope*.

**Papain** is a nitrogenous body, isolated from the juice of the tropical *Papaw* (q.v.). The juice from which it is extracted is a milky, white, odorous fluid, obtained by making incisions in the ripe fruit. From this papain is isolated by precipitation with alcohol after the latter has been removed. The juice has been for a long time used in the West Indies for making meat tender; but it has only recently been shown that papain possesses, like peptic and trypsin, the power of digesting meat-fibre; and this digestion will go on in an alkaline, a neutral, or an acid solution. Hence it belongs to the group of digestive enzymes, and like them is employed in some cases of dyspepsia, being either administered internally or employed for the pre-digestion of food. It has also been used for the removal of warts and for the solution of the ‘false membrane’ in cases of diphtheria.

**Papal States.** See *Church (States of the)*.

**Papaveraceae**, a natural order of exogenous plants, herbaceous or half shrubby, usually with a milky or coloured juice. These plants are alternate,
without stipules; the flowers on long, one-flowered stalks. The fruit is pod-shaped or capellar, the seeds numerous (see PAPAVER), and is distinguished for narcotic properties. Opium (q.v.) is its most important product. The juice of Cel- 
aldine (q.v.) is very acrid. The Blood-root or Sanguinaria (q.v.) is another representative of the one genus native to their northern countries for medicinal purposes. The seeds yield fixed oil, which, with the exception of that obtained from Argyemone Mexican, is quite bland. The flowers of many species are large and showy, most frequently white or yellow, sometimes red. There are seeds known to be abortive in all quarters of the world, and of tropical and temperate climates, but they abound most of all in Europe.

Papaw (Carica papaya), a small South American tree of the natural order Passifloraceae (formerly made the type of a small family, Papavaceae), which has now been introduced into many tropical and subtropical countries. The fruit is eaten either raw or boiled. The seeds when chewed have in a high degree the pungency of cresses. The powdered seeds and the juice of the unripe fruit are more powerful antihelminths. The juice of the fruit and the sap of the tree render tough meat tender (see Bapaw); (see also the explanations on the tree have this property, and joints of meat, fowls, &c. are hung among its branches to prepare them for the table. It bears fruit all the year, and is exceedingly prolific. The Chambara (C. digitata), another species of the same genus, a native of Brazil, is remarkable for the extremely acrid and poisonous character of its juice, and the disgusting stereocœaneous odour of its flowers. — In the United States the name Papaw is given to the Asimina triloba, a small tree of the natural order Annonaceae, the fruit of which, a large oval berry, 3 inches in length, insipid pulp, is esteemed by negroes, but not generally relished by others. All parts of the plant have a rank smell.

Papenburg, a small port in the north-west of the province of Hanover, 25 miles W. of Oldenburg by rail and near the Emms, with which it is con- nected by canals. Pop. 6,916. In the neighbourhood are extensive moors.

Paper. The earliest paper was doubtless that made in Papaw, Papaya, whenever all similar writing material is named. The paper used to be described as being made of the thin pellicle lying between the rind and the pith; now it is known to have been made of slices of the cellular-pith laid lengthwise side by side, whereas other layers were laid crosswise, the whole moistened with Nilo water, pressed and dried, and smoothed by being rubbed with ivory or a smooth shell. The papyrus paper was superseded in Europe by paper of other fibrous matter gradually between the 6th and 11th centuries (see PALEOGRAPHY). At a remote antiquity the Chinese made paper of the bast of a special mulberry-tree, of sprouts of bamboo, and of Chinese grass (see BERSHEBA). According to Fang Mi-Chih, author of the Encyclopaedia Tung-yu, the Chinese at first wrote on bamboo-boards; but for 300 years before and after Christ the name was written on paper made of silk-waste, solidified in some way not described. The inventor of paper made of vegetable fibre was the statesman Ts'ai Lun, born in Kwai-yang, in the province of Hun-nan, who in 80 a.d. was in charge of the eel arsenals. In 105 a.d. it is expressly testified that he had succeeded in making paper of bark, of hemp, of rags, and of old fishing-nets. The governor of Samarkand, returning from a victorious expedition into China in 751 a.d., brought back amongst his prisoners of war artisans who enabled him to establish a paper manufactory at Samarkand. Hero Persians learned the mystery, and soon were making paper. Its manufacture rapidly increased, and new paper-works were at work in 795 at Bagdad, where the manufacture was carried on till the 15th century. Soon paper-making was practised in Damascus, Egypt, and the countries of Africa; and ere long this paper, to which the names of paper and papyrum were transferred, was imported into Europe, where it was generally known as Charta Damascus, bombeyina, cuttana, and gossypina. From the latter adjectives it has since been held that the earliest paper was made of wood, and not of cotton-wool, and that this was only gradually superseded by rag pulp. But the researches of Wissner and Karabacek on 12,500 MSS. brought to Vienna from the Fayum in 1854 by Archiduke Rainer have proved that this is an error. There never was any paper made by Arabs from cotton-wool; the charta cuttana was all made of rags, and called 'cottony,' probably only from its resemblance to fine cotton cloth. The first manufacture of rag paper in Europe was in Spain under the Moors; in 1134 there was a mill at Jativa. But soon after traces of paper-making were found in Italy, France, and Germany. In England there is said to have been a paper-mill at Stevenage in Hertford in 1460, but little is known of the history of paper-making in England till about 1638, when there was a wellknown mill at Dartford. Rag paper had, however, been commonly in use since the 14th century at least.

The art of paper-making is one of the most useful that has been invented, and paper has acquired a degree of importance with which it would not have been credited in the 18th century. It has been well observed that paper has contributed more to the advancement of the human race than any other material employed in the arts, and its manufacture constitutes an industry depending more closely than any other on the march of civilisation. Its uses are now beyond number; the demand for it is so general that it has become an article of prime necessity, and one that is daily entering more and more largely into the ordinary wants and ordinary life of all classes. Large as the make of paper is in the United Kingdom, it is not applied to so many and general uses as paper and paper-pulp is in the United States, Japan, and some of the other countries. In the expansion of other mechanical industries, there has been great progress made in the last half-century. Chemists and mechanics have each contributed their part. The former have furnished improved methods for washing, bleaching, and colouring the paper stock, which must yield a different product from what was made by the ancients; while the mechanical improvements also have been many, both for boiling, running out, drying, and finishing the pulp. The vegetable substances from which paper can be made are numerous, but the difficulties are to obtain them at a sufficiently low price to be used profitably and to secure a continuous supply. Many books and newspapers have been printed entirely of one material, such as bamboo, straw, jute, Phormium tenax, maize-leaves, and so on. In the Exhibition of 1880 a paper-maker showed more than sixty webs or rolls of paper, each made from a different vegetable fibre. Books, again, have been published which were composed of several hundred leaves, all of a different fibre. In Japan a species of mulberry-tree is extensively grown for paper-making. But the substances available in Europe are few that can be had in quantity at a low price. The multitude of vegetable fibres that have been suggested for the use of the paper-maker is
bewildering, but of the number only two have come into use to any general extent; these are esparto and wood-pulp. The best sources of fibre for the paper-maker's use are linen and cotton rags for white paper, and hempen cordage for brown; but they have been found by experiment that rags are no longer available in sufficient quantities for paper-making. Having regard to the composition of the paper, the supply would at first seem to be illimitable, inasmuch as woody fibre is amongst the most common of vegetable things. Mr T. Routledge in his report to the London Exhibition in 1851, and other people since, have given the principal impetus to the use of wood-pulp. At first the wood is simply rubbed down into pulp against the periphery of a wheel with a rough surface; but now by improved chemical appliances a better pulp is produced, and the manufacture has become generally adopted in Europe and America, a misleading large proportion of the world's paper being made from this material. Wood-pulp is admirably adapted as a principal ingredient in the manufacture of cheap paper. It is deficient in fibre, but a moderate admixture of rags, esparto, or other fibrous material strengthens it. It was not until 1873 that wood-pulp began to be manufactured in England as a paper material. At first only 12,000 tons could be got rid of yearly, but in 1890 as much as 137,837 tons was received, chiefly from Sweden and Norway. Much of the paper made is used up a second time. Koop's patent for reworking old waste-paper was carried on in the earlier years of the 19th century at the Neckinger Mills, Bermondsey. The process of manufacture then would seem to have been faulty, the paper made being unfit for use, and the mill was sold. The process has, however, been brought extensively into use of late years, and many improvements have been made. The quantity and value of the paper materials received by Britain in 1889 were:

The idea of making a paper-pulp of wood was repeatedly mooted in the early part of the 19th century. A patent was granted to some paper-makers in Italy in 1826. Some years later the idea was revived in improvements in Great Britain by Desgrand, Johnson, Newton, and others. Mr Houghton took out a patent in 1857. But the mechanical process of Voelter of Heidenheim was that which gave the principal impetus to the use of wood-pulp. Esparp is treated much like straw, but does not require so much soda-ash and chlorine to bleach it. The fibres are easily dissolved and bleached by chemical process. They form readily and yield an excellent pulp, which is employed alone, or mixed with rags, wood-pulp, or straw. It furnishes a paper plain, resistant, transparent, and of great purity, thicker than other papers of the same weight, and forming a good printing and writing substance.

The culms of various cereal grasses are employed where obtainable; rice-straw in Asia, wheat, oat, and other kinds of straw in Europe. Straw was used a century ago for paper-making, but its extensive use is comparatively recent. For many years it commands a market, but as a mixer it is inferior to esparto, the internodes or knots being exceedingly troublesome and difficult to get rid of. The deficiency in the supply of rags and the abundance of esparto has become so great that the industry of esparto has led to a great run upon wood-pulp in the last few years for the paper-mills in Great Britain and most other countries. Its manufacture and use dates practically back only to about 1870; indeed its general adoption may be referred to the same year. Although esparto is not so generally adaptable as the most valuable papers, they can be used as a substitute for them. Wood-pulp is used in many cases, and in the manufacture of some papers, such as kraft or china clay. Very often 25 to 30 per cent. of such substances is introduced into these loaded papers, which do for cheap journals, the sheets of which have hence no solidity. But if such papers...
are used for book-work they have no durability, and are also injurious to the type. Another cause which contributes quite as much to the bad quality of many modern papers is the too rapid destilation which the sheets undergo in the preparation of machine-made paper. Admitting that many of the papers now made are infinitely finer, more beautiful, and above all whiter than those made in former ages, it is evident that in both respects machine-made papers possess less strength than the old hand-made papers. Paper of pure and good quality ought not to leave after burning more than 2 per cent. of ash.

The question for consideration as to the future is whether raw material enough can be obtained in quantity to keep our mills going, since esparto must gradually fail, and wood-pulp and rags will alone remain to us, unless some new, cheap, and abundant vegetable fibre can be met with. About 90,000 tons of rags are collected in Britain, but they are chiefly of cotton fabrics, and even these are now much drawn upon for other purposes. How much longer will Belgium, France, and Germany be disposed to part with their rags? and without rags wood-pulp is useless, however plentiful it may be.

The pulp is made up of fibres, easily separated from each other, and being thus naturally divided the following four classes: (1) news and printing papers; (2) writing-papers of various kinds, blue, cream, and yellow laid, and wove and tinted, and for account-books, &c.; (3) wrapping or packing papers, brown and purple, heavy manilla for cartridge and bags (4) sheet or writing paper, made from such light copying tissue, and pottery papers, blotting and filtering, cigarette, &c.

Lastly, there are all kinds of cardboards and millboard. The making of these follows the principal kinds of papers, &c. made in the British mills; but the list might be extended to one or two thousand varieties of various kinds and qualities. Account-book, backing, bag-papers, bank-note and bill, blottings, boards, board-papers, browns (heavy and cutting), letter, caps (brown for bags), cards for looms, carpet-felt, cartridge, engravings, chart-papers, cheques, cigarette, collar, coloured, coverings, draft-papers, drawers, drawn, dyers, engine boards (glazed and milled, paste and portmanteau), envelope-paper, filtering, fly-papers, foil or tin-foil, grocery, gun-wadding, hosiery, lithographic, lions, long elephants, manilla, manillas, marbled, mottled, brown, mill wrappers, music or printings, parchments, paper, pipes, postal, press, rough, rate-way-ticket, royal hands (gray, brown, blue, and white), smoking, slips, small hands (browns), teapaper, tissues, tobacco, tracings, tube-paper, waterproof, wrapping, writing. It is on record that in 1772 there were sixty varieties of paper made from as many different materials, and ten or twelve years later the number had been extended to 103. In those days all paper was manufactured by hand, each sheet separately. The rags were pulped in mortars by trip-hammers, and several days were required to turn out a sample of dry finished paper. The workman dipped a rectangular sieve on, mould into the vat and deposited the sheet of fluid pulp on a piece of felt to dry.

This simple mode of manufacture, which is still largely practised in Holland and Italy, has been superseded generally by calenders and only a small quantity of paper for special books, editions-de-luxe, and the like, besides a superior writing, bank-note, and drawing paper is now made by hand in England. Millboards (g.v.) and pasteboard or cardboard were formerly chiefly made for bookbinding; but now they are much in demand for box-making, machine, packaging, and other purposes. Over 50,000 tons of straw and wood board are imported from Germany, Holland, Belgium, and other countries, besides what is made in Britain.

The various machines for making paper in continuous lengths are wonderful productions of mechanical skill, and although lagging behind the corresponding perfection, and they work with marvellous exactness. These machines consist of contrivances for causing an equal supply of pulp to flow upon an endless wire-ganze apron, which revolves and carries on the paper until it is received on an endless sheet of felt, paper, or various kinds of non-adhesive cylinders. These machines have now been brought to such perfection that paper can be made in one continuous roll or web of any length, and before leaving the machine is sized, dried, calendered, hot-punched, and cut into sheets.

At the Edinburgh Exhibition in 1886 a web of paper was shown five miles long, and at the Pittsburgh Exhibition there was a roll 14 miles long, 18 inches wide, which weighed 2658 lb. Some of the machines are 70 to 100 feet long and 120 inches wide, requiring a building 200 by 300 yards, and a sheet of paper 7 feet in width.

Fig. 1 is a side-view of a continuous paper-making machine, and fig. 2 a vertical one. The principle of the machine is very simple: it contains a pulp-vat, A, with a hog or wheel inside to agitation to pulp, and on the right the following the following five classes: (1) news and printing papers; (2) writing-papers of various kinds, blue, cream, and yellow laid, and wove and tinted, and for account-books, &c.; (3) wrapping or packing papers, brown and purple, heavy manilla for cartridge and bags (4) sheet or writing paper, made from such light copying tissue, and pottery papers, blotting and filtering, cigarette, &c.

Lastly, there are all kinds of cardboards and millboard. The making of these follows the principal kinds of papers, &c. made in the British mills; but the list might be extended to one or two thousand varieties of various kinds and qualities. Account-book, backing, bag-papers, bank-note and bill, blottings, boards, board-papers, browns (heavy and cutting), letter, caps (brown for bags), cards for looms, carpet-felt, cartridge, engravings, chart-papers, cheques, cigarette, collar, coloured, coverings, draft-papers, drawers, drawn, dyers, engine boards (glazed and milled, paste and portmanteau), envelope-paper, filtering, fly-papers, foil or tin-foil, grocery, gun-wadding, hosiery, lithographic, lions, long elephants, manilla, manillas, marbled, mottled, brown, mill wrappers, music or printings, parchments, paper, pipes, postal, press, rough, rate-way-ticket, royal hands (gray, brown, blue, and white), smoking, slips, small hands (browns), teapaper, tissues, tobacco, tracings, tube-paper, waterproof, wrapping, writing. It is on record that in 1772 there were sixty varieties of paper made from as many different materials, and ten or twelve years later the number had been extended to 103. In those days all paper was manufactured by hand, each sheet separately. The rags were pulped in mortars by trip-hammers, and several days were required to turn out a sample of dry finished paper. Over 50,000 tons of straw and wood board are imported from Germany, Holland, Belgium, and other countries, besides what is made in Britain.

The various machines for making paper in continuous lengths are wonderful productions of mechanical skill, and although lagging behind the corresponding perfection, and they work with marvellous exactness. These machines consist of contrivances for causing an equal supply of pulp to flow upon an endless wire-ganze apron, which revolves and carries on the paper until it is received on an endless sheet of felt, paper, or various kinds of non-adhesive cylinders. These machines have now been brought to such perfection that paper can be made in one continuous roll or web of any length, and before leaving the machine is sized, dried, calendered, hot-punched, and cut into sheets.

At the Edinburgh Exhibition in 1886 a web of paper was shown five miles long, and at the Pittsburgh Exhibition there was a roll 14 miles long, 18 inches wide, which weighed 2658 lb. Some of the machines are 70 to 100 feet long and 120 inches wide, requiring a building 200 by 300 yards, and a sheet of paper 7 feet in width.

Fig. 1 is a side-view of a continuous paper-making machine, and fig. 2 a vertical one. The principle of the machine is very simple: it contains a pulp-vat, A, with a hog or wheel inside to agitation to pulp, and on the right the following five classes: (1) news and printing papers; (2) writing-papers of various kinds, blue, cream, and yellow laid, and wove and tinted, and for account-books, &c.; (3) wrapping or packing papers, brown and purple, heavy manilla for cartridge and bags (4) sheet or writing paper, made from such light copying tissue, and pottery papers, blotting and filtering, cigarette, &c.

Lastly, there are all kinds of cardboards and millboard. The making of these follows the principal kinds of papers, &c. made in the British mills; but the list might be extended to one or two thousand varieties of various kinds and qualities. Account-book, backing, bag-papers, bank-note and bill, blottings, boards, board-papers, browns (heavy and cutting), letter, caps (brown for bags), cards for looms, carpet-felt, cartridge, engravings, chart-papers, cheques, cigarette, collar, coloured, coverings, draft-papers, drawers, drawn, dyers, engine boards (glazed and milled, paste and portmanteau), envelope-paper, filtering, fly-papers, foil or tin-foil, grocery, gun-wadding, hosiery, lithographic, lions, long elephants, manilla, manillas, marbled, mottled, brown, mill wrappers, music or printings, parchments, paper, pipes, postal, press, rough, rate-way-ticket, royal hands (gray, brown, blue, and white), smoking, slips, small hands (browns), teapaper, tissues, tobacco, tracings, tube-paper, waterproof, wrapping, writing. It is on record that in 1772 there were sixty varieties of paper made from as many different materials, and ten or twelve years later the number had been extended to 103. In those days all paper was manufactured by hand, each sheet separately. The rags were pulped in mortars by trip-hammers, and several days were required to turn out a sample of dry finished paper. The workman dipped a rectangular sieve on, mould into the vat and deposited the sheet of fluid pulp on a piece of felt to dry.

This simple mode of manufacture, which is still largely practised in Holland and Italy, has been superseded generally by calenders and only a small quantity of paper for special books, editions-de-luxe, and the like, besides a superior writing, bank-note, and drawing paper is now made by hand in England. Millboards (g.v.) and pasteboard or cardboard were formerly chiefly made for bookbinding; but now they are much in demand for box-making, machine, packaging, and other purposes. Over 50,000 tons of straw and wood board are imported from Germany, Holland, Belgium, and other countries, besides what is made in Britain.
produce a glossiness of surface. For writing-papers the paper passes through a shallow trough of size after leaving the drying cylinders, and then passes over another series of skeleton cylinders, with fans moving inside, by which it is again dried without heat, and afterwards passes through the calenders. Printing and other papers are usually sized by mixing the size in the pulp, in which stage the colouring materials—such as ultramarine for the blue tint of foolscap—are also introduced. Still following the paper web in the drawing (fig. 1), it is seen to pass from the calenders to another machine, P; this cuts the web into widths, which are again cross-cut into sheets, the size of which is regulated at will. In the United States, for fine book-work, the paper receives a white coating after it has been made; it is the finish thus given to the surface that renders the illustrations seen in the best American magazines possible. The watermark is impressed on machine-made paper by means of a fine light-wire cylinder with a wire-woven pattern; this is placed over the wire-gauze sheet upon which the pulp is spread, but near the other end of it, so that the light impression of the marker may act upon the paper just when it ceases to be pulp, and this remains all through its course. There are many other interesting points about the paper-machine, but their introduction here would rather tend to confuse the reader. Its productive power is very great; it moves at a rate of from 20 to 290 feet per minute, spreading, couching, drying, and calendering as it goes, so that the stream of pulp flowing in at one end is in two minutes passing out finished paper at the
other. It has been computed that an ordinary machine, making webs of paper 54 inches wide, will turn out four miles a day.

Paper Production of the World.—The following is the currently accurate return of the paper-mills of Europe in 1890, and their annual production:

Many of the mills may not be working, some produce only, and the vat-made paper is included in the estimate of production. Assuming 1 million tons are made annually, this may be valued at £300,000,000, of which half is the prime cost of the raw material.

It is difficult to determine with any precision the quantity of paper now made in the United Kingdom, as the manufacture is free from tax; but we may form a fair estimate by looking at the progress under the duty rate, and judging of the advance since from the increased exports and the machinery now in use. The following are official figures of the quantity of paper charged with duty before the abolition of the tax, which brought in £1,500,000. In 1842, 43,166 tons; 1852, 70,000 tons; 1861, 102,456 tons. In 1851 Mr Poole, in his [Statistics of British Commerce], stated that there were then 457 paper-mills at work in the United Kingdom; 349 in England, 48 in Scotland, and 40 in Ireland. The weight of paper made amounted to 62,000 tons; the estimated value of which was £3,500,000. The number of mills in 1850 was 397; in 1870, 369. Mr W. Arnott, in his course of lectures on the Technology of the Paper Trade before the Society of Arts in 1877, stated the number of paper-mills working in the United Kingdom at 385; of which 300 were in England, 65 in Scotland, and 20 in Ireland. The production of paper made in the kingdom was about 520, producing 350,000 tons of paper, which, with 10,000 tons of hand-made, gave a total production of 360,000 tons. This quantity he estimated to be worth £16,000,000 sterling. This is, however, far too high an estimate, having regard to the depreciated prices resulting from the fall in value since 1850. The 400,000 tons made at the present time cannot be valued at more than £12,000,000. Assuming the annual production of paper in the United Kingdom at present to be 400,000 tons, the home consumption is evidently large and growing, for we now import in books and paper about 57,000 tons, while we import of writing and printing papers, &c., 60,000 tons. Newspapers, books, and periodical literature use up fully one-half of our total make. Schools and public offices and correspondence consume much of the writing and printing paper, and the remaining paper is used for wrapping, packing, and other purposes. Judging from the data adduced, the British paper-manufacture has more than quadrupled since the abolition of the paper-duty.

The export trade of the United Kingdom in paper has been rapidly progressive, as the figures in the following table will show; the first of its two columns comprising writing-paper, printing-paper, and envelopes; and the second all other kinds of paper.

The average price of paper, which in 1874 was as high as £22 per cwt., has fallen as low as 30s. per cwt. The superiority of the British over the continental manufacture has obtained for Britain a steadily increasing business in the markets of Asia, South America, and her Colonies. In 1879 the value of the British paper of all kinds exported was £915,925; in 1880 £1,180,000; and in 1881 £2,080,000 at the usual lower prices ruling. In 1880 was imported of paper and pasteboard of all kinds 2,110,000 cwt., an increase of 1 million cwt. over 1882.

In the United States equal progress has been made in the paper-manufacture as in Great Britain. The first mill was established in 1690, on ground now included within Philadelphia. In 1770 there were forty paper-mills in Pennsylvania, New Jersey, and Delaware, and only three or four in New England. In 1840 there were in the United States but 425 paper-mills; in 1850, 500, producing 60,000 tons; in 1872 there were 812 mills, owned by 705 firms, making 200,000 tons. At present, with over 1000 paper-mills having 3000 machines, the quantity made greatly exceeds that of the United Kingdom; the amount since the decade 1870-80 amounting to over 1,200,000 tons. In the other parts of America there are 85 paper-mills. In Asia there are 19 paper-mills, besides numerous vats; in Africa, 4; and in Australasia, 7; making a total of nearly 5000 mills in the world. The production of hand-made papers in China and Japan it is impossible to estimate. China has made great strides in her exports of paper of all kinds. From about 75,000 cwt. a few years ago the export advanced to 237,000 cwt. in 1890, valued at £350,000. The greater part of the paper now made in the world—at least three-fourths—is believed to be used for printing on, since the correspondence carried on in many countries out of Europe is comparatively small.

There are works on paper and paper-making by Hofmann (New York, 1873), Munseil (New York, 1870), Archer (1876), and Desbarbes (1858, 1867); T. T. Davis (1886), and Crans and Bevan (1887). For old water-marks dating from 1475, see Archéologie, vol. xii. For ancient paper-making, see Hirch, Chinischen Studien (1890), and Riecke, Die Geschichte des Papiers. WALLER in the subject of a separate article.

Paphlagonia, anciently a province of Asia Minor, extending along the southern shores of the Black Sea, from the Halys on the east to the Parthenius on the west (which separates it from Bithynia), and inland on the south to Galatia. Its limits, however, were somewhat different at different times, and it successively belonged to Lydia, Persia, and Rome. Its capital was Sinope. The Paphlagonians are supposed to have been of Syrian or Semitic origin, like the Cappadocians.

Paphos, two ancient cities in Cyprus. Old Paphos (now Ayfka) was situated in the western part of the island, about 14 mile from the coast. It was probably founded by the Phoenicians, and was famous, even before Homer's time, for a temple of Venus, who was said to have here risen from the sea close by, whence her epithet Aphrodite, 'foam-sprung.' This was the home of the 'Paphian Diana,' who received crowds of votaries there. The other Paphos (Papho or Bapho) was on the seacoast, about 8 miles west of the older city, and was the place in which the apostle Paul proclaimed the gospel before the proconsul Sergius.

Papias, Bishop at Hierapolis, in Phrygia, in the earlier half of the 2d century, is known to us only from references by Irenæus, Eusebius, and a
few others, and from fragments of his lost work preserved in the writing-books especially Essebinius [Hist. Ecl. iii. 39]. Irenaeus speaks of him as a ‘hearer of John’—evidently meaning the apostle. Essebinius aptly quotes Papias himself against Irenaeus on the point; but, while the quotation justifies his criticism thus far, it does not fully exonerate the writer that he had never been a hearer of two other disciples of the Lord, Aristion and the elder (not the apostle) John. There is, then, no very reliable evidence of personal intercourse with any of the immediate followers of Jesus. On the other hand, some of the links between the Gospels and early apocalyptic literature are known; for two daughters of the apostle Philip, living in Hierapolis, related traditions to him, and he was a ‘companion of Polycarp’ (99-155 A.D.), Bishop at Smyrna, who in his youth had been a disciple of the apostle John. The statement, however, in the Chronicon Paschale, that Papias suffered at Pergamum in the year of this contemporary’s martyrdom at Smyrna, rests on the compiler’s mis-reading of Essebinius [Hist. Ecl. iv. 15].

The only work which he is known to have written is the Excerpta e Prophetis (especially ‘Oracles of the Lord’), in five books, which on various grounds, including an expression in a fragment recently discovered, may be probably assigned to the period 140–150. It is now generally agreed that the signification of ‘oracles’ is not to be absolutely limited to discourses, and that by ‘Oracles of the Lord’ we are to understand a record, or records, of the Lord’s sayings, including at least a setting of narrative. Part of the author’s design was to supplement his expositions with traditional or specially-preserved quotations. But the scanty remains are enough to show that Papias was, as Essebinius says, ‘of very small intellect,’ credulous, and fond of recording the wonderful. His doctrinal characteristic is a quaint millenarianism, with traces of the Apocalypse of Baruch.

But it is in relation to the New Testament canon, and especially to what is known as the synoptic problem, that Papias is of real importance. The fragment bearing on Mark runs thus: ‘This also the elder (John) said: ’Mark, having become the interpreter (recorder) of the four (Synoptie) gospels, recorded in so many words the words he remembered, without, however, recording in order what was either said or done by Christ.’ &c. Many scholars maintain that the words suit the second gospel as we have it, while others who deny this accept them as an account of its groundwork. Still greater interest attaches to the short fragment on Matthew: ‘Matthew, then, composed the oracles in the Hebrew (Aramaic) language, and each one interpreted them as he could.’ This statement has often been called in question, but the best authorities now hold that Papias was correct as to the Aramaic original, and that the canonical gospel, while evidently not a translation, is a Greek edition, by either Matthew himself or some writer unknown. On the whole, the two-document hypothesis of the origin of the synoptics, which at present holds the field, coincides remarkably with the above two fragments (see GosPELS). As to the rest of the canon, Papias quoted 1 John and 1 Peter, and was cited as an authority for the ‘credibility’ of the Apocalypse. There are also statements concerning the Apocalypse.

For Papias generally, see Lightfoot, Essays on the Work entitled ‘Supernatural Religion’ (1889); for the collected fragments, the Patrum Apost. Opera of Gebhardt, Har- nack, and Zahn; for an English translation, the Ante- Nicene Fathers.

PAPIAS: TAPIER-MACHE (Fr., ‘mashed or pulp paper’). This name is applied to a material consisting either of paper-pulp or of sheets of paper pasted together, which by a peculiar treatment resembles varnished or lacquered wood, and is used for example for the decoration of a cabinet of this kind. The art of paper-mache was in Persia and next to it in Cashmire. The articles chiefly made are cases for pens and other writing materials, as well as boxes and trays. In Japan various objects are manufactured by gluing together a number of sheets of the paper, the whole being then cut out and pasted together upon moulds, when it is in a damp state. This kind of paper-mache, which is light, strong, and elastic, was at one time used in that country for helmets and other parts of armour. No doubt it was from one or other of these eastern countries that the art of working in paper-mache was acquired by Europeans.

Articles of paper-mache were extensively made in France in the first half of the 18th century. Subse- quently the manufacture was largely developed in Germany, where paper-mache was used for boxes, boxes and other articles termed Vernis Martin work, from the fact that they were made by a coach-painter named Martin, who had a peculiar way of varnishing them, were in the 18th century popular throughout Europe, and fine specimens are still sought after by collectors. Paper-mache appears to have been introduced into England for the purpose of imitating Japanese trays of lacquered wood. In 1772 Henry Clay of Birmingham took out a patent for making paper-mache of sheets of paper, pasted together upon a mould. In this way he produced panels for doors and walls, besides cabinets, screens, tables, tea- trays, &c., and these are still manufactured. The best paper-mache is made by Clay’s method; but it is also made from paper-pulp to which glue has been added, and this is pressed between dies to give it the required shape. There is a third kind made of coarse fibrous material, mixed with earthy matters and a binding size, certain chemicals being added to render it incombustible. Suppose that a heavy-blank of hardened sheets has been placed upon a metal mould. It is then heated to 120° F., and afterwards dipped in a mixture of linseed-oil and spirits of turpentine (other mixtures are used) to harden it and make it resist moisture. It is again placed in a stove, and when taken out it is planed and filed to give it the required finish. The tray now gets several coats of varnish and lampblack, each of which is rubbed down with pumice, and stoved once more. It is then ready to be decorated, after which it receives a coat of transparent varnish, and is finally polished with the hand.

Carton-pierre, which has been extensively em- ployed for the internal decoration of buildings (much in the same way as plaster), is formed of paper-pulp mixed with whiting and glue, and pressed into plaster moulds. It is next backed with paper, allowed to set, and dried in a hot room. Ceramic Paper-mache (Martin’s patent dated March 15, 1856) is a very plastic substance, which can be readily moulded or otherwise worked into any required form. It is composed of paper- pulp, resin, glue, drying oil, and sugar of lead, well kneaded together.

There are various ways of decorating paper- mache. For tea-trays, caskets, panels, and other objects with a black varnished surface, what is called ‘inlaying’ with plates of mother-of-pearl shell, sardine, and mother-of-pearl has been largely practised. The pieces of shell are stuck on with varnish, and the design painted on them with a protecting varnish. An application
of acid dissolves away the unprotected parts, and then the interspaces are filled up with varnish. When the surface is rubbed with pumice-stone the superfluous varnish is removed which leaves the shell ornaments displayed. In a similar way the surface can be "inlaid" with cut-ont-metal devices. Flower and landscape painting has also been much employed in the way of decoration, as well as borders and other ornaments in leaf gold. Owing to the excellence in results obtained in cheap Japanese lacquer wares (see LACQUER), the Birmingham manufacturers of papier-mâché have now largely resorted to an inexpensive decoration by transfer-printing, which can be done by boys and girls instead of highly-paid artists. A change has also taken place in the nature of the material itself, which has recently been chiefly made of wood-pulp from Sweden. A limited quantity of the old high-class papier-mâché is, however, still regularly manufactured. The variety of papier-mâché adopted for architectural ornaments, which are usually more or less in relief, can be readily painted, gilted, or bronzed. The application of papier-mâché to articles requiring great strength, such as wheels for railway carriages, has not proved so successful as was at one time anticipated.

Papilionaceae (from Lat. papilio, 'butterfly'), a sub-order of the natural order of plants generally included within the Scrophulariales (q.v.), the plants of which have flowers of the peculiar structure called papilionaceous, and of which the Pea and Bean afford familiar examples. Papilionaceous flowers have five petals, imbriicated in estivation (bud), one of which, called the vexillum, or standard, is superior, turned next to the axis, and in estivation folded over the rest; two, called the alar, or wings, are lateral; and two are inferior, which are often united by their lower margins, forming the corona, or keel. The number of the Papilionaceae is very great—about 400 species being known. They are found in all parts of the world, abounding in the tropics. Many have superb and beautiful flowers; many are plants of beautiful form and foliage, trees, shrubs, or herbaceous plants; many possess valuable medicinal properties; and many are of great use as furnishing material for man and for domestic animals, others as furnishing dyes, fibre, timber, &c. See BROOM, LABURNUM, CLOVER, BEAN, PEA, LUCERN, LIQUORICE, INDIGO, SANDALWOOD, &c.

Papillae. See SKIN, TASTE.

Papin, Denis, a French physicist, was born at Blois, 22d August 1647, and studied medicine in Angers, where he practised for some time as a physician. But, becoming acquainted with Huygens, he helped him in his experiments with the air-pump; then, crossing to England, he assisted Boyle in his physical experiments, invented the condensing pump and the steam digester (1681)—a sort of steam cooking apparatus, to which was appended a still, and so made a member of the Royal Society (1689). Shortly afterwards he proceeded to Venice for the purpose of helping to conduct a newly-founded Academy of science, but was back in London in 1684. Three years later he was appointed physicist to the Council of Mann. At Mann from 1696 to 1707 worked in Cassel. Then, returning to England, he died in obscurity, probably in 1712.

To Papin belongs the honour of having first applied steam (1690) to produce motion by raising a piston, and with this he combined the simplest means of producing a vacuum beneath the raised piston—viz. by condensation of aqueous vapour. In virtue of this his biographer claims that he is really the inventor of the steam-engine. He is the inventor of the safety-valve, an essential part of his digester; of the siphon; and according to some, of steam-navigation. See SHIPBUILDING, p. 402; also DIGESTER.

His papers were mostly printed in the Philosophical Transactions of the Royal Society (London, 1690) and the Journal des Sçavans, &c. He also wrote Nouvelles Expéríences du Vide (Paris, 1674). See Lires by Eroult (Paris, 1874) and Gerland (Berlin, 1851). His correspondence with Huygens and Sekelkost was published by Gerland (Berlin, 1851). See Nature, vol. xxiv. (1881).

Papinbuch, Louis Joseph, Canadian statesman, was born at Montreal in October 1789. At twenty he was elected to the Legislative Assembly, and speedily worked his way to the head of the Radical or French-Canadian party, and in 1815 was chosen speaker of the House of Assembly for Lower Canada, a post that he held until 1837. He opposed the union of Upper and Lower Canada, formulated the grievances and demands of his party in the Ninety-two Resolutions, and agitated actively against the imperial government. When the province rose in 1837, a warrant was issued against Papineau for high-treason, though he took no active part in the fighting. He escaped to Paris; but returned to Canada, pardoned, in 1847. He died at Montebello, in Quebec, on 23d September 1871.

Papiabiaus, Aemilius, down to the time of Justinian the most celebrated of the Roman jurists, was created a senator in 394 and consul in 400 with Severus, whose second wife is said to have been his relative. Both he and Septimius were pupils of Scevola; Papinianus succeeded the prince as aedoucatus fisci, and afterwards held the office of prefectus praetorio. The son and successor of Severus, when he died, caused Papinianus to be put to death in 212. His works consist of 37 books of Questions, 19 of Responsa, 2 of Definitiones, and De Alituribus; from these works 655 excerpts were incorporated in Justinian's Pandects.

Pappenheim, Gottfried Heinrich, Count von, an imperial general of great note in the Thirty Years' War, was born at Pappenheim, in Middle Frankonia, Bavaria, in 1554, of a very ancient Swabian family, in which the dignity of Marshal of the Empire became hereditary about the 13th or 14th century, and many of whose members had greatly distinguished themselves in the wars of the middle ages. At twenty he went over to the imperial Catholic Church, and thenceforth signalised himself by his fiery zeal in its cause. After serving under the king of Poland in his wars with the Russians and Turks Pappenheim joined the army of the Catholic League, and in the battle of Prague (1620) stayed the flight of the Austrian cavalry, and by a well-timed and furious charge turned the tide of battle against the Bohemians. In 1623 he received from the emperor the command of a cavalry regiment of the famous 'Pappenheimer Dragonen.' In 1625 he became general of the Spanish horse in Lombardy; but in 1626 he re-entered the Austrian service, and after suppressing a dangerous revolt of the peasants of Upper Austria, in which 40,000 of the peasants perished, he joined the army which was opposed to the Protestant League, and, in association with Tilly, carried on some of the most brilliant campaigns against the Saxons. It was Pappenheim who judiciously Tilly to attack Magdeburg (q.v.), and on his head rests in great measure the guilt of the ferocious massacre. His reckless bravery involved Tilly against his will in the disastrous battle of Breitenfeld; but to some extent he retrieved his character by his benevolent efforts to remedy the loss and protect the retreat of the army. After Tilly's death he served under Wallenstein, who detached him with eight regiments to protect Cologne, but, on hearing of the advance of Gustavus, sent an urgent order for his
return. Papenheim arrived at Lützen at the moment when Wallenstein’s army was on the point of being completely routed, and at the head of his cuirassiers he charged the left wing of the Swedes, with such fury as to throw it into confusion, and for a moment restrained the fortune of the battle. He was mortally wounded in the last charge, and died a few hours afterwards at Leipzig, November 7, 1632, with a smile on his countenance, after learning that Gustavus Adolphus was dead. ‘God be praised!’ he said: ‘I can go in peace, now that that mortal enemy of the Catholic faith has had to die before me.’

**Pappus.** See *Composite.*

**Pappus of Alexandria** flourished about the end of either the 3rd or the 4th century A.D. Which of these dates is the more probable it is difficult to determine, owing to conflicting evidence, but recent opinion inclines to the former. Suidas states that Pappus was a contemporary of Theon, thus placing him towards the end of the 4th century, and ascribes several treatises to him. These treatises have not survived, and the only work by which Pappus is now known, his *Mathematical Collection*, receives no mention from Suidas. This work consisted of eight books, the first and the earlier part of the second of which are lost, and its interest is mainly, though not exclusively, historical. From what remains of the second book, it is conjectured that the first two books were arithmetical. The third book explains some of the methods for the duplication of the cube, treats of the progressions and the five regular polyhedra. The fourth book discusses the figure called the arbelos (‘a shoemaker’s knife’), the spiral of Archimedes, the conchoid of Nicomedes, and the quadratrix of Dinostratus. The fifth book contains some theorems regarding isoperimetrical figures plane and solid, and a short account of the semi-regular solids of Archimedes. The sixth book comments on some of the works of Theodosius, Aristarchus of Samos, and Euclid. From the seventh book, which is the longest and most valuable of the *Collection*, is derived a large part of our knowledge of Greek geometry. Many of the writings here analysed are no longer extant, and it is on the indications (in the notable instance of Euclid’s *Porisms*, the very obscure indications) which Pappus gives of the object or the contents of them that the geometers of the 17th and 18th centuries relied for their restorations of these writings. The eighth book is devoted mainly to mechanics. The mathematical interest of the *Collection* does not equal the historical, but several of the books contain important theorems, the discovery of which is probably due to Pappus himself. One of the long lists, concerning the names of the months, is attached, and is called the name of Guldinus (1557-1643). Some others have received a brilliant development from the mathematicians of modern times. The last six books of the *Mathematical Collection* were translated into Latin by his own disciple, and were published in 1588; another edition appeared in 1600. Fragments of the Greek text have been printed at various times in England, France, and Germany, but the only complete edition is that of Fridericus Hultsch, *Pappus Alexandrinus Collectionis Quae Superservit* (3 vols., Berlin, 1876-78).

**Papua.** See *New Guinea.*

**Papules,** or *Pimples,* are ‘solid small elevations of the skin,’ and may be either pale in colour or inflammatory and more or less red. *Papules* occur as an early stage in the development of the eruption in many skin diseases—e.g. in eczema, where they speedily become vesicles; or in acne, where they become pastules. The popular diseases proper, where the eruption in its fully developed form consists of papules, are lichen and prurigo.

**Paprus,** a genus of plants of the natural order Cyperaceae, of which there are several species, the most important being the Egyptian *Paprus* or *Papyrus* of the ancients (*P. antiquorum*, *Cyperus papyrus of Linnaeus*)—a kind of sedge, 8 to 10 feet high, with a very strong, woody, aromatic, creeping root, long, sharp-pointed leaves, and naked, leafless, triangular, soft, and cellular stems, as thick as a man’s arm at the lower part, and at their upper extremity bearing a compound umbel of extremely numerous drooping spikelets, with a general involucre of eight long filiform leaves, each spikelet containing six to thirteen florets. By the ancient Egyptians it was called *papu,* from which the Greek *paprus* is derived, although it was also called by them *byblis* and *deltos.* The Hebrews called it *gome,* a word resembling the

*Coptic gom, or ‘volume;’ its modern Arabic name is *berdi.* The plant is nearly extinct in Lower Egypt, but is found in Nubia (whence it was probably introduced into Egypt and Abyssinia. It still grows in the Jordan Valley, in the neighbourhood of Jaffa, and also of Sidon, in parts of the Sinai Desert, and in Sicily. It is often a conspicuous feature in African vegetation. It is represented on the oldest Egyptian monuments, and as reaching the height of about ten feet. It was grown in pools of still water, growing ten feet above the water, and two beneath it, and restricted to the districts of Sais and Sebennytus. The *paprus* (not merely *P. paprus,* but *P. dives,* which is still found in Egypt) was used for many purposes, both ornamental and useful, such as wraths for the head, sandals, boxes, boats, and cordage, but the *P. paprus* was valued principally for a kind of paper called by its name. Its pith was boiled and eaten, and its root dried for fuel. The *paprus* or *Paper* (q. v.) of the Egyptians, made of strips of its pith in layers, was of the greatest reputation in antiquity, and it appears on the earliest monuments in the shape of long rectangular sheets, which were rolled up at one
end, and on which the scribe wrote with a reed called kash, with red or black ink made of car
animal carbon. When newly prepared it was white
or brownish white and lissom; but in the process
of time those papyri which have reached the present
day have become of a light or dark brown colour,
and exceedingly brittle, breaking at the touch.
Papyrus was also used in Egypt for the pur-
purpose of writing, and was, in fact, the paper of the
period; but, although mentioned by early Greek
authors, it does not appear to have come into
general use among the Greeks till after the time
of Alexander the Great, when it was extensively
exported to Egypt from the Ptolemaic ports under
the Romans. It was, however, always an expen-
sive article to the Greeks. Among the Romans
it does not appear to have been in use at an early
period, although the Sibylline books are said to
have been written on it. It was cultivated in
Catalonia, Apulia, and in the marshes of the Tiber;
but the staple was no doubt imported from Alex-
andria. So extensive was the Alexandrian manu-
factory that Hadrian, in his visit to that city, was
struck by its extent. It continued to be employed
in the eastern and western empire till the 12th
century. It was then almost entirely superseded
by parchment, but was, in the 18th; but after that period it was quite superseded
by parchment or by paper made of rags. During
the later periods it was no longer employed in the
shape of rolls, but cut up into square pages, and
bound like modern books.
The discovery in Egypt of classical Greek authors
written on papyri began about the middle of the
19th century, and the results have been on the
whole beyond expectation. The great orator
Hyperides (q.v.), then only known by name, is
now reproduced in four or five complete
mss.; fragments of Euripides and Alcman
have been added to what we possess of these authors, and early MSS. have been obtained of
parts of Homer, Plato, Thucydides, Demostenes,
and Isocrates. In 1888-90 Mr Flinders Petrie
found near Medinet Habu and Fayum marshes which
were identified as fragments of Plato's Phaedo, tran-
scribed about 250 B.C., and a part of the lost
Antiope of Euripides, besides quantities of letters
doing the Ptolemaic period. In January
1918 there were 160 mummy cases (dating from the
26th Dynasty) were found in a sub-
terranean passage at Deir el Bahari, near
Thebes; with these were many papyri, contain-
ing, as usual, many ritual passages and extracts
from the Book of the Dead (q.v.); there were also
boxes crammed with papyri. And at the begin-
ing of the same year the world was surprised
by the announcement that papyri rolls obtained
from Egypt by the British Museum authorities
had been found to contain almost the whole of
a lost but famous work of Aristotle on the
constitution of Athens. Of these rolls there were
four, of which the longest measures seven feet,
the shortest three feet. They have been written
by four different copyists, are mainly in a small
semi-cursive hand, and date from about the end
of the 1st century A.D. There are thirty-six
columns, and were discovered in the Arable
fields. The text was edited and published in
February 1891 by Mr F. G. Kenyon; a later edition
which cuts off Marajo Island from the mainland,
pours in part of the waters of the great river.
Pará (official name Beten), a thriving city and
seaport of Brazil, capital of the state of the same
name, stands on the east bank of the river Pará, 70
miles from its mouth, on a point of land formed by
the entrance of the Guandú. The harbour is
nearly landlocked by wooded islands, and admits vessels
of large size. Pará, as a whole, is a plain-looking
commercial centre, but, compared with the
straggling suburbs, the dense tropical forest coming
close up to the outskirts. The streets are narrow,
but regular, well shaded with mangoes and palms,
and partly paved; many of the houses, with their
white and white-tiled roofs and whitewashed walls,
are very pretty. The theatre, market, and
church are in general use, and there is a railway to Bragança
(108 miles). The principal buildings are the
theatre, the government building, custom-house,
and cathedral (1729). The city contains a small forts
and botanical gardens. The place is not unhealthy,
though the wet season extends over nearly two-
thirds of the year. Pará, the headquarters of
the 'Amazonian Steamboat Company' and others, is
the emporium of the Amazon river-trade, supplying
the towns of the interior with foreign goods,
and exporting produce such as piau, pirus, anacardes,
pirarucu fish, &c. The annual value of the exports
exceeds £2,500,000. Pop. 50,600. See Vincent,
Around and About South America (1890); and
Brazil, and books there noted.—The state,
bordering on Guiana and the Atlantic, and divided by
the Amazon, has an area of 448,620 sq. m., with a
pop. (1925) of 335,000. 'Para Grasso' is a name
given to piassava; see FIBROUS SUBSTANCES.
Para, a coin of copper, silver, or mixed metal,
though mostly of copper, in use in Turkey
and Egypt; it is the 40th part of a Piastre (q.v.),
and varies much in value, owing to the debased
condition of the Turkish coinage.
Parable (Gr. parábóλé, 'a comparison') was
originally the name given by the Greek rhetoricians to an illustration knowingly introduced as such. In
Hellenistic and New Testament Greek it came
to signify an independent fictitious narrative,
employed for the illustration of a moral rule or principle. This kind of illustration of eastern
origin, and the greatest example to be found
in the Old and New Testaments, particularly in
the discourses of our Lord. The parable differs from
the fable in the probability or verisimilitude of the
story itself, and agrees with it in the essential
requisites of simplicity and brevity. It is essen-
tially a short allegory marked by probability of incident,
and intended to convey one direct moral
or spiritual truth. In the course of time the word
parable came to lose its significance of figurative
speech, and to mean speech generally.
There are works on the parables of our Lord by Arch-
bishop Trench (1846), Calderwood (1860), A. R Bruce
(1852), Goebel (trans. 1853), and Dods (1883). See also
the articles ALLEGORY, ATOLIAGE, and FABLE.
Parabola, the section of a cone by a plane
which is parallel to a generating line. As a
particular case, when the plane passes through
the vertex of the cone, the plane comes close up into a
straight line. A property of the parabola is that
the distance of any point on the curve from a
certain fixed point is equal to its distance from
certain fixed straight line. The fixed point is
called the focus of the parabola, the fixed
line is called its directrix. In the figure, PAP
represents a parabola of which S is the focus and BC
is the directrix. The point A is called the vertex
of the parabola. The line ASO is the principal
diameter of the curve; and any line drawn through a point
such as 1 parallel to AO is called a diameter.
From the above property it is easy to prove that \( PN^2 = 4AS\cdot AN \), where \( N \) is the foot of the perpendicular from \( P \) upon \( OA \). It is obvious that the parabola is not a closed curve. The centre (corresponding to the centre of the ellipse) is situated at infinity. The tangent at \( P \) bisects the angle \( SPD \). Hence a reflecting surface formed by the intersection of \( PAP \) about \( OA \) as axis is such that parallel rays falling upon it in the direction of \( OS \) are reflected to \( S \). Conversely, rays diverging from \( S \) will be reflected parallel to \( SO \). Hence the intensity of light at \( O \) from a radiant beam of light remaining constant at all distances from the source, except in so far as it is affected by absorption, and the parabolic is therefore the most perfect form of reflector (Lighthouse, Reflection). If the resistance of the air were negligible, the path of a projectile would approximately be a parabola with its axis, or principal diameter, vertical, and its vertex at the highest point of the path. Let \( PN = y \), \( AN = x \), \( AS = a \). The equation of the parabola referred to its vertex as origin is \( y^2 = 4ax \). All curves the equations of which are of the form \( y^2 = px^2 \) are classed as parabolas. Thus, the curve represented by the equation \( y^2 = px \) is called the\( eubical parabola \); and that one whose equation is \( y^2 = px^3 \) is called the \( semi-eubical parabola \).

Paraboloid is a solid figure traced out by a Parabola (q.v.) revolving round its principal axis.

Paracelsus, a name coined for himself by Theophrastus Bombastus von Hohenheim, was, apparently meant to imply that he was greater than Celsus; there is no good authority for further adding the names Philippus Aureolus. Paracelsus was the son of Williem Bombast von Hohenheim, a physician at Einsiedeln, in the Swiss canton of Schwyz, and was born in 1493 or 1494 (it seems impossible to decide which). He owed his early education mainly to his father; went to Basel University at sixteen, but soon left to study alchemy and chemistry with Thurnheim, Bishop of Würzburg; and next at the mines in Tyrol belonging to the Fugger family learned the physical properties of metals and minerals, and the disposition of rock strata, and began to realise that the observation of nature is of surpassing greater value to the student than academic lectures or the lucubrations of the study. Here and in subsequent wanderings over great part of Europe he amassed a vast store of facts, learned the actual practice of medicine amongst various peoples, but lost all faith in scholastic disquisitions and disputations. He acquired no little fame as a medical practitioner, and on his return to Basel in 1526 received the appointment of town physician. He also lectured on medicine at the university, but defied academic tradition not merely by lecturing in German (not Latin), but by flouting at Gellen and Avice- na—burning their books in public, as was affirmed—and denying all that was most firmly believed by the faculty.

Bitterness, backbiting, enmities soon rose and pursed him throughout the rest of his life, aggravated and justified in some measure by his own vanity, arrogance, and aggressiveness, as also by his intemperate habits. A dispute with the magistrates in 1528 led to his leaving Basel in haste; he wandered for more than a dozen years, visiting Colmar, Nuremberg, Zurich, Augsburg, and many other towns, sojourning more than a few months, and at last settled in 1541 under the protection of the archbishop at Salzburg. But he died on the 24th September of the same year—murdered by his enemies, said his friends; in consequence of a drunken debauch, said his enemies.

He is said to have written some 304 works, of which only some 230 were printed; and of these the critics only admit from ten (Marx) to twenty-four (Häser) as genuine, the others being by his followers; the 'Paracelsists.' They were mainly written in Swiss-German, the Latin versions being by other hands. About a dozen were translated into English. The earliest printed work was Practica D. Theophrasti Paracelsi (Augsburg, 1529). Collected German editions appeared at Münster in 1536-41 (11 vols. folio); and at Wittenberg, 1543-5 (4 vols. folio; re-issued 1618), Latin editions in 1603-5 (11 vols. folio) and 1628 (Geneva, 3 vols. folio).

His system was based on a cosmogonic view of the universe, the disturbances in the economy of the human body being determined by the movements of the all-embracing macrocosm. Repudiating the current pseudo-Aristotelianism, Paracelsus turned sympathetically to Neoplatonism and the Cabala; but it seems difficult not to admit in him an element of pure charlatanism, as well as of mysticism. Unquestionably, however, his method and his influence tended in the direction of the immediate observation of nature, the discarding of antiquated theories, the encouragement of independent research, experiment, and innovation. He is not to be blamed like his age to Alchemy (q.v.); he certainly made some new chemical compounds, and applied chemical knowledge to improve pharmacy and therapeutics, and, in an empirical fashion, to revolutionise hide-bound medical methods.

See monographs by W. B. Lessing (1839), Marx (1842), Mook (Würzburg, 1841); the articles: Paracelsus; and the History of Medicine by Häser. There is an English Life of Paracelsus by F. Hartmann (1886); Brownings famous poem on Paracelsus is well known.

Paralute (Fr. chenê, 'a fall'), a machine for the purpose of deranging the velocity of descent of any body through the air, and employed by aeronauts as a means of descending from Balloons (q.v.). The original type was a gigantic umbrella, strongly made, and having the outer extremities of the rods, on which the canvas is stretched, firmly connected by ropes or stays to the lower part of the handle. It was recommended in 1783 at Lyons by Le Normand as a means of escape from a house on fire, but was first used in connection with ballooning by Blanchard in 1793. In 1887 Baldwin claimed to have ascended from Paris by one of these means of a paralute in 31 minutes.

Paralute. See SPIRIT (HOLY), MONTANISM, AHELARD.

Paradise (Gr. parádeisos, 'a park, 'a pleasure-ground,' originally an oriental, apparently Persian, word; cf. the Heb. pardes, and modern Persian, firâvon), the garden of Eden (q.v.), Heaven (q.v.).—See BIRD OF PARADISE for the bird so named.

Paradise-fish (Macropodus viridis aureus), a Chinese species. Macropus was first kept in aquariums for its beauty of form and colouring. In the male the colours increase in brilliance at the pairing-season, and he swims around his mate in a kind of dance around its head, flapping the long, delicate filaments of the ventral
The paradox (Gr. para, 'beside' or 'beyond,' and do, 'to'), used to signify whatever is contrary to the received belief; not necessarily an opinion contrary to truth. There have been bold and happy paradoxes whose fortune it has been to overthrow accredited errors, and in the course of time to become universally accepted as truths. For paradoxists who square the circle, and invent perpetual motion, see Quadrature of the Circle, Perpetual Motion; and De Morgan's Budget of Paradoxes (1872).

Paradoxes Bed (Paradozidan), a term sometimes applied to the Harlech and Longmynd and Menervian rocks of Britain, which are characterised by their abundance of paraffin-wax, and belonging to the genus Paradoxia. See Cambrian System.

Paraffin (so called as being parum affinis —i.e. having little affinity—for an alkali) is first named by Baron Reichenbach (q.v.) to a white transparent crystalline substance first obtained by him in 1830 from wood-tar. The honour of this discovery must be shared with C. W. Beilby, who independently, and almost simultaneously obtained the same body in making a chemical examination of Rangoon petroleum, and which he named petrolene. Dumas, a French chemist, obtained it also from coal-tar in 1833. But for twenty years after its discovery paraffin-wax remained a chemical curiosity only. It was not till 1850 that it began to be produced, by Mr James Young, in quantity sufficient to occupy the attention of manufacturers. Since then it has become of great importance commercially. For years paraffin-wax was the principal material employed in the manufacture of camphene in Great Britain and Germany, having for that purpose, to a large extent, superseded the use of beeswax, spermaceti, stearic acid, and stearine, besides being used in many other branches of the arts and manufactures, and in surgery.

The word paraffin, at first applied by Reichenbach to the solid body, is now used by chemists as a generic term for the series of saturated Hydrocarbons (q.v.), the higher members of which are paraffin-wax, lower members are liquid, and the lowest are gases; usually called being lower oils. Paraffin oil was the term first employed by Mr Young to denominate the mineral burning oils produced by him, and this name still applies in Britain to all the oils associated with the manufacture of paraffin. In these oils, however, the oleine series of non-saturated hydrocarbons is largely represented along with liquid paraffins. But Petroleum (q.v.) is the term in general use to designate the natural oils of America, Russia, and other countries, which are for the most part mixtures of these same two series of hydrocarbons. As the production of paraffin-wax and paraffin oils has now become an industry of great importance to the world, it will be convenient to make some reference here to the history of its development, particularly in Scotland, which is now the seat of the industry. To a limited extent coal and shale or shist are made use of in Germany, in France, in Italy, and in Australia for the production of hydrocarbon oils.

In December 1847 Mr James Young received a letter from Dr (Sir Lyon) Playfair, calling his attention to the fact that a limited supply of liquid petroleum existed at Alfreton in Derbyshire. On examining this oil Mr Young recognised the commercial importance of the products that could be obtained from it. He erected a refinery, and produced a light oil for burning, a heavy oil for lubricating, and paraffin-wax. This petroleum spring, at first producing about 300 gallons per day, had exhausted itself at the end of two years. Meanwhile, Mr Young, collecting on the probable origin of the oil, and after a series of experiments, succeeded in distilling at a low heat an analogous oil from coal. This process became the subject of his celebrated patent obtained in 1850. Works were erected at Bathgate, in Scotland, in which he neighbourhood a large amount of coal was at that time being mined for gas-making. It was known as Torbaniehill Mineral or Boghead Coal (q.v.). This mineral was employed by Mr Young, and it yielded under distillation about 120 gallons of crude oil per ton. In 1852, at Bathgate, he had the price of this coal was 13s. 6d. per ton, and it gradually rose, till in 1862 it stood at 90s. per ton, when the simply ceased. Mr Young's patent, which covered the distillation of oil from coal at a low red heat, ran from 1850 to 1864. In 1859, however, Mr Robert Bell erected oil-works at Broxburn (q.v.), in which he distilled oil from shale. He was the first in Scotland to use this material, although Du Buisson had obtained a patent in France previous to 1850 for the distillation of schist or shale. Since 1862 this mineral has been, and now is, the principal material employed in Scotland for oil-making. Soon after Mr Young obtained his patent in 1850 he granted licenses for its use in the United States of America, where oil for several years was distilled from canal-coal; but public attention being thereby directed to the natural petroleum it was soon reduced to a mere scullery abundance, the use of canal-coal was discontinued. Mr Young was thus the pioneer not only of the paraffin-oil manufacture, but also of the petroleum industries of the world.

During the progress of the shale-oil industry in Scotland it has been frequently subject to serious vicissitudes of fortune, more than once being threatened with extinction. During one of those periods of depression about 1872 the Welsh coal-oil trade collapsed entirely. The Scotch industry was saved from a similar fate by the energy and inventive resource of some of the persons engaged in it. The history of the trade naturally falls into various periods, and during these periods articles of manufacture that were considered by-products, and regarded of little value, or for which there was no marked market, afterwards became of such importance that they were even unknown earlier to be of such advantage the life of the trade. The first period was a brief one (1848–50), when Mr Young utilised the petroleum-spring at Alfreton for the production mainly of lubricating oil, used in mills as a substitute for sperm-oil. The second period extended over the duration of Young's patent (1850–64), when the burning oil had become of the greatest importance to the manufacturer. The third period (1864–72) witnessed the great development of the petroleum trade in America, during which the price of burning oil fell so low that about half of the works in Scotland were closed. The fourth period (1872–78) was a period of severe struggle for existence. The smaller and weaker works disappeared. The production became concentrated in fewer hands with larger outputs. Burning oil being now less remunerative, the trade was most attended to the recovery of all waste-products and to the development of the by-products; paraffin-wax and sulphate of ammonia then becoming of chief importance to the manufacturer. Fortunately also the inventive abilities of Mr. Henderson, of William Young, of James A. and George T. Bemrose, culminated in the production of new and economical processes whereby manufacturing costs were reduced, and the yield of the products that had now become of most value much increased. The fifth period (1879–87) was
PARAFFIN 749

in consequence a time of much prosperity, ending, however, in a partial collapse by reason of overproduction in Scotland combined with ever-increasing imports of cheaper oil from abroad. From 1877, for a few years from 1887, was a period of combination, the Scotch and American producers having combined to restrict the supplies of paraffin wax. After 1894 the Scotch companies suffered again from American (and after Russian) competition.

Geologically, the position of the shale in the east of Scotland is in the Lower Carboniferous series, but in the west of Scotland it is found in the ordinary coal-measures. There are some seven or eight different seams of shale, all varying in position and quality from each other; but the same shale also varies from its normal character in different districts, being thick and rich in one place, and thin and poor in another. The Broxburn seam of shale at its best is probably the richest and most profitable graviity to work; but the Pumpherston seams of shale, though poor in oil, have now become of value, because they are rich in ammonia. The shale is procured in the same manner as in coal-mining.

The following summaries will indicate the material facts in the history of the trade in Scotland, and the direction and extent to which the improved processes have tended—viz. diminished yield of burning oils, increased yield of lubricating oils, paraffin-wax, and sulphate of ammonia, together with reduction of loss in process of manufacture.

The first most notable improvement was the Henderson retort, patented by N. M. Henderson in 1873. With this retort the spent shale off which the oil had been distilled, and which still contained about 12 per cent. of carbon, was allowed to descend into the retort beneath, where a very high boiling fraction of specific gravity 1.000 is obtained and its solidifying point is then exposed to a current of steam and air; this method gives a greatly increased yield of ammonia; and it is therefore a form of retort of the utmost value in the case of shales rich in nitrogenous and poor in bituminous products.

This was followed in 1883 by Mr Henderson's continuous distillation process, in which the crude oil passes by gravitation through three stills. During the progress of the oil through these stills the fractionation or separation of the crude oil into naphtha, burning oil, and heavy or lubricating oil containing paraffin takes place automatically. In addition to these three stills there are two or more coking stills into which alternately the residue of the crude oil flows and where the distillation is completed, the dry coke being removed from each at regular intervals. The advantages obtained from this process are saving in first cost of plant, saving of labour, time, and fuel; less cost of maintenance; the fractionation of the oil is more perfect and uniform, and the distillates purer, giving less loss in refining. Mr Henderson obtained this by a patented process, greatly simplified and cheapened the cost of the production of sulphate of ammonia. And his new methods of refrigeration and refinement of the crude paraffin scale increased the yield of wax and improved the quality of the lubricating oils.

In the distillation of bituminous minerals for the production of gas a bright-red heat is employed in order to obtain as much incomendable vapour or permanent gas as possible. The aim of the oil manufacturer on the contrary is to minimise the production of incomendable gas, and to obtain the highest possible percentage of the liquid and solid hydrocarbons. He therefore reduces the distillation temperature to the lowest practicable point—viz. from 600° to 800° F.

Crude oil is composed of a very wide range of hydrocarbons, each varying in specific gravity and boiling point, and in the percentage of carbon present; but in the practical operations of the refiner the fractionation of the oil is confined within certain definite limits which have been found of most convenience commercially—viz. Naphtha, 40° to 150° F.; distillation oils, 150° to 300° F.; commodity, 300° to 400° F.; lubricating oils, 400° to 600° F.; soaps, 600° to 800° F.; and such products as are obtained from the distillation of crude oil at high temperatures, for example asphalt, pitch, and soles.

The operations in the production and refinement of mineral-oil products stated briefly are:

The shale when taken from the pits is broken into small pieces and put into the retorts. In the retort the first chemical process, destructive distillation, takes place. The various products of the oil-works do not exist as such in the shale; they are all created by the destructive distillation. The shale, according to quality, yields from 20 to 40
gallons of crude oil per ton, and over 60 gallons of ammonia water. This water, now such a valuable product to the oil-manufacturer, was allowed for years to go to waste; but in 1864 was for the first time utilised by Mr. Bell, who recovered ammonia from it by the sulphate.

The operations of the oil-refinery are: (1) distillation, (2) treatment with chemicals, (3) cooling and pressing the heavy oil containing paraffin so as to separate the solid hydrocarbons from the liquid.

The oils are distilled several times and are fractioned into various classes, and between each distillation the oil is treated with oil of vitriol and caustic soda. After the finishing treatment with acid and soda some of the soda compounds are obtained in solution by the oil; these have to be carefully removed by washing with water. The absence of acid and alkaline compounds, and thorough fractionation of the oil, are the great secrets in the refining of burning oils; and at some of the works in Scotland the best burning oils that can be obtained are now produced, and the deposits of which oil can be obtained.

In lubricating oils the essential features are high viscosity, high flash-point, and low setting-point. The first two depend on proper fractionation; and the third is secured by careful refrigeration, so that the lowest forms of solid paraffin may be crystallised and separated from the liquid.

The crude paraffin scale or wax is refined either by chemicals, by sweating, or by treatment with naphtha. The chemical treatment is seldom used, the greater portion being purified under the sweating process, which is simple and effectual.

The temperature of the sweating-chamber is raised from 2° to 3° above the setting-point of the paraffin required; the oil then drains off, carrying most of the other impurities with it. But the best qualities of refined paraffin require a treatment or two with strong naphtha. The paraffin is melted about 30 per cent, of spirit run in, and after careful stirring together the mixture is allowed to cool down; it is then pressed, when the naphtha runs out, taking the matter out with it. This pressed paraffin is again melted and steam blown through the giving off the remainder of the naphtha, and finally the melted paraffin is stirred with animal charcoal, settled, and then filtered through cloth and filter-paper, and run into pans to solidify into cakes of convenient size.

**Paraguay, an island republic of South America, divided into two distinct portions by the river which bears its name. Eastern Paraguay, or Paraguay proper, is a well-defined territory, nearly in the shape of a parallelogram, from 22° to 27° 30' S. lat. and 54° to 58° 40' W. long., bounded on the N. by the rivers Apa and Estrella, on the E. by the mountains-clains of Amambay and Mbaracayú, and by the river Paraná, and on the S. by this same river. It contains an area of about 142,000 sq. m., a territory considerably larger than Great Britain and Ireland. The territory of Paraguay is composed of whites of Spanish descent, Indians, a few negroes, and a mixture of these several races, and in 1895 was estimated at 500,000, exclusive of the Indians in the Chaco. A mountain-clain called Sierra Mbaracayú, running in the general direction of north to south, and bifurcating to the east and west towards the southern extremity, under the name of Sierra Mbaracayú, divides the tributaries of the Paraná from those of the Paraguay, none of which are very considerable, although they afford fine pastoral and productive overflows. The northern part of Paraguay is in general undulating, covered by low, gently-welling ridges, separated by large grass plains, dotted with palms. There are mountains in the north-east and north-west corners.

The southern part of the country, in the marshes and marshy parts of the Chaco, desert part of South America, consisting of hilly and gentle slopes richly wooded, of wide savannahs, which afford excellent pasture-ground, and of rich alluvial plains, some of which, indeed, are marshy, or covered with shallow pools of water (only one of which is the Paraná, desert part of South America, consisting of hilly and gentle slopes richly wooded, of wide savannahs, which afford excellent pasture-ground, and of rich alluvial plains, some of which, indeed, are marshy, or covered with shallow pools of water (only one of which is the Paraná), or Paraguay, one of the chief articles of commerce, being in general use throughout great part of South America. The shrub or tree grows wild in the north-eastern districts, and the gathering of its leaves gives employment in the season to a large number of the

**Paraguay, an island republic of South America, divided into two distinct portions by the river which bears its name.** Eastern Paraguay, or Paraguay proper, is a well-defined territory, nearly in the shape of a parallelogram, from 22° to 27° 30' S. lat. and 54° to 58° 40' W. long., bounded on the N. by the rivers Apa and Estrella, on the E. by the mountains-clains of Amambay and Mbaracayú, and by the river Paraná, and on the S. by this same river. It contains an area of about 142,000 sq. m., a territory considerably larger than Great Britain and Ireland. A mountain-clain called Sierra Mbaracayú, running in the general direction of north to south, and bifurcating to the east and west towards the southern extremity, under the name of Sierra Mbaracayú, divides the tributaries of the Paraná from those of the Paraguay, none of which are very considerable, although they afford fine pastoral and productive overflows. The northern part of Paraguay is in general undulating, covered by low, gently-welling ridges, separated by large grass plains, dotted with palms. There are mountains in the north-east and north-west corners.
native population. Native orange woods are common, and more than fifty million oranges are exported annually. Many trees also yield valuable gums. Wax and honey are collected in abundance, as is also cochineal, and the medicinal plants are very numerous. The chief cultivated crops are maize, rice, coffee, coca, indigo, maniez, tobacco, and sugar-cane.

The animal world is largely represented in Paraguay, and game, both large and small, is very abundant. Tapirs, jaguars, pumas, ant-eaters, wild-boars, pheasants, and deer of many descriptions are inhabitants of the forests and plains; birds are innumerable, and for beauty and variety of plumage none can compare in the world; the rivers teem with fish, and their banks are the resort of alligators and crocodiles. Snakes are numerous, but very few of them are venomous. Some of the bees are exceedingly large, and there is a remarkable water-serpent which is said to sometimes attain a length of eight yards.

The commerce of the country greatly increased during the decade 1880-90, and several banks and other mercantile institutions have been established. In 1880 the total value of exports was £1,000,000, and in 1889 £1,900,000; their respective values were £507,903 and £344,037. In this latter year the total revenue was £824,935, and the expenditure somewhat in excess. The chief exports are yerba-mate, tobacco, hides, oranges, timber, bark for tanning, and lace; the imports, wool, flax, glassware, wine, grain, rice, linen, silk, petroleum, &c. Trade in the towns is almost wholly in the hands of Italians, French, and Germans. The principal native industries are tanning and the manufacture of pottery and bricks, laces, ponchos, soap, fool-pastes, brandy, &c.

The railways of the republic were 907 in 1885-70. Paraguay had no national debt, but the utter ruin into which it had then fallen compelled it to have recourse to foreign aid. Two loans were contracted in London in 1871-72, the nominal amount of which was three millions sterling, but only about one-half was placed. The republic defaulted in 1874, but at the end of 1883 a settlement was made with the bondholders whereby the loans were reduced to the sum of £380,000 bearing 2 per cent. interest at the commence ment, and gradually increasing to 4 per cent. In 1891, however, the public lands were ceded to the republic in payment of arrear interest. The service of the new debt has been regularly maintained. There are also obligations or polizas assigned as an indemnity to Brazilian and Argentine subjects for losses sustained by them during the war. The total external indebtedness amounts to £4,794,308. There is no internal debt. The military force consists of 500 men. The established religion is the Roman Catholic, the ecclesiastical head of which is the Bishop of Asuncion. Education is free and compulsory; but of the adult Paraguayans only one in five can read and write.

The history of Paraguay is highly interesting. It was discovered by Juan Diaz de Solis in 1515, and further explored by Diego de Gama in 1522, and by Sebastian Cabot in 1520; but the first colony was settled in 1533 by Pedro de Mendoza, who founded the city of Asuncion, and established Paraguay as a province of the viceroyalty of Peru. The warlike native tribe of the Guaranis, having possessed a degree of civilization, and professed a dualistic religion, long successfully resisted the Spanish arms, and refused to receive either the religion or the social usages of the invaders. In the later half of the 16th century the Jesuits were permitted to the aid of the first preachers of Christianity in Paraguay: but for a long time they were almost entirely unsuccessful, the effect of their preaching being in a great degree marred by the profligate and cruel conduct of the Spanish adventurers, who formed the staple of the native population. In the 17th century the home government consented to place in the Jesuits' hands the entire administration, civil as well as religious, of the province, which, from its not possessing any of the precious metals, little value as a source of revenue; and, in order to guard the natives against the evil influences of the bad example of European Christians, gave to the Jesuits the right to exclude all other Europeans from the colony. From this time forward the progress of civilization was as well as the growth of the population of the province. In 1670 the expulsion of the Jesuits from Paraguay in 1675, the history of which is involved in much controversy, the province was again made subject to the Spanish viceroy. For a time the fruits of the older civilisation maintained themselves; but as the ancient organisation fell to the ground great part of the work of so many years was undone, and by degrees much of the old barbarism returned. In 1776 Paraguay was transferred to the newly-formed viceroyalty of Rio de La Plata; and in 1810 it was joined with the province of Buenos Ayres. In 1811 the independence of the mother-kingdom of Spain, which, owing to its isolated position, was the earliest of them all to establish completely. In 1814 Dr Francia (q.v.), originally a lawyer, and the secretary of the first revolutionary junta, was proclaimed dictator for three years; and in 1817 his term of the office was made perpetual. He continued to hold it till his death in 1840, when anarchy ensued for two years; but in 1842 a national congress elected Don Mariano R. Alonzo and Don Carlos Antonio Lopez, a nephew of the dictator, joint chiefs of the consuls of the republic. In 1845 the Republic of Argentina was proclaimed, and Don Carlos was elected sole president, with dictatorial power, which he exercised till his death in 1862, when he was succeeded by his son, Don Francisco Solano Lopez, whose name has become notorious in connection with the tragic struggle of 1863-70, in which the Paraguayans made a heroic but unavailing fight against the combined forces of Brazil, the Argentine Confederation, and Uruguay. The war was brought to a close by the defeat and death of Lopez at the battle of Pavón (1870). After the taking of Asuncion, the rest of the war may be read in the returns of the population—(1857) 1,337,439; (1873) 221,079, including only 28,740 men and 106,254 women over fifteen years of age. The sexes are now, however, again nearly equal. Paraguay's share of the general emigration of recent years from Europe to South America; and in every way the country has made considerable progress. In June 1870 a congress voted a new constitution, which was proclaimed on the 26th November. It is modelled on that of the Argentine Confederation, the legislative authority being vested in a congress of two houses, and the executive in a president, elected for four years. A curious feature in the recent history of the state is the settlement here of 500 Australian Socialist workmen, one colony of whom was thriving in 1896.

Asuncion, the capital, had in 1893 a population of 45,000, and has a railway 160 miles in length, designed ultimately to connect with the Argentine railway system.

Paraguay, capital of the Brazilian state of Paraguay, on the river of the same name, 10 miles from the sea. Its chief buildings are the cathedral and the government palace (formerly the Jesuit college). A large sugar-mill was erected in 1889. At the mouth of the river is a bar; but a railway (12 miles) was built in 1889 to the port of Cabel- dello, there terminating in a pier in deep water. The annual exports—sugar, cotton, and coconuts—chiefly to Great Britain; amount to about 100,000. The state, the easternmost in the republic, has an area of 28,854 sq. mi. and a pop. (1890) of 457,282. — There is a more important Parahyba River farther south, which enters the Atlantic, in the state of Rio de Janeiro, after a course of nearly 500 miles. It is navigable for 50 miles from its mouth.

Parallax is the apparent displacement of an object caused by a change of place in the observer. When an object at M is looked at from P it appears in line with some object, S; but after the observer has moved to E, M has apparently moved to a position in line with S' the amount of apparent motion is called parallax. The angle PME is called the angle of parallax, or the parallactic angle; and is the measure of the amount of parallax. To astronomers the determination of the parallax of the heavenly bodies is of the utmost importance, for two reasons: first, from the necessity of referring all observations to the earth's centre—i.e., so modifying them as to make it appear as if they had been actually made at the earth's centre; and secondly, because parallax is our only means of determining the magnitude and distance of the heavenly bodies. The geocentric or daily parallax—i.e., the apparent displacement of a heavenly body, due to its being observed from a point on the surface of the earth instead of from its centre, is called is determined as follows: Let P and P' be two stations on the surface of the earth (fig. 2), E its centre, M the object to be observed, and Z and Z the zeniths respectively of the observers at P and P' (points which, if possible, should be on the same meridian exactly); then at P and P' let the zenith distances, ZPM and ZP'M', be observed simultaneously, and since the latitudes of P and P', and consequently their difference of latitude, or the angle PEP', is known, from these the angle PMP' (the sum of the parallaxes at P and P') is at once found; and then, by a trigonometrical process, the separate angles or parallaxes PME and P'M'E. When the parallax of M, as observed from P, is known, its distance from E, the centre of the earth, can be at once found. When the heavenly body is on the horizon, as at O, its parallax is at a maximum, and is known as the horizontal parallax. The geocentric parallax is of use only in determining the distance of those heavenly bodies at which the earth's radius subtends a considerable angle.

In the case of the fixed stars, at which the earth's radius subtends an infinitesimal angle, it becomes necessary to make use of a much larger base-line, the earth's radius, and, as the largest we can employ is the radius of the earth's orbit, it accordingly is made use of, and the displacement of a star, when observed from a point in the earth's orbit instead of from its centre, the sun, is called the annual or heliocentric parallax. Here the base-line, instead of being, as in the former case, 4000 miles, is about 92,000,000 miles, and the two observations necessary to determine the parallactic angle are made from two points on opposite sides of the earth's orbit, at an interval as nearly as possible of half a year. Yet, notwithstanding the enormous length of the base-line, it bears so small a proportion to the distances of the stars that only in a few cases have they been found to exhibit any parallactic motion whatever, and very rarely does the angle of parallax amount to 1° (see Stars). The geocentric or daily parallax is an angle about 57° 43' 25"; that of the sun, about 8° 38'; and of the double star, 61 Cygni, the heliocentric parallax has been determined by Bessel to be 345", equivalent to about 15 millionths of a second of geocentric horizontal parallax. See the articles Stars and Sun.

Parallel Forces are forces which act in parallel lines, such as for example as the weights of the portions that make up any framework or structure on the earth's surface. With the exception of a particular case (see Couple), parallel forces have always a single resultant, which is readily found by the method of moments. See Moment; also Force.

Parallel Motion, a name given to any linkage by which circular motion may be changed into straight line motion. The most familiar instance is Watt's parallel motion (see Steam-engine), which is essentially a three-bar linkage, and, although not theoretically perfect, is sufficiently good for all practical purposes. It is impossible, indeed, to obtain a straight line motion without the use of at least five bars in the linkage; and till 1874, when Hart discovered the method, even this simplest mode of obtaining a true parallel motion was not deemed possible. The Peaucellier's linkage, a linkage of seven bars, was, however, the earliest linkage discovered for solving the problem of how to draw a straight line. It dates from 1864, and is, perhaps, the most convenient form that has yet been devised. It is shown in the figure. The equal links AP, AQ, BP, BQ, form a rhombus; the long links OA, OB, are also equal, and have the common point O fixed. The seventh link, QC, has its end C fixed to A, Q describes a circle passing through O—i.e., QC equals the fixed distance CO. In these circumstances, when Q moves in its circle P moves in a straight line. See A. B. Kempe's How to draw a Straight Line ("Nature" series, 1877).

Parallelogram of Velocities. See Composition.
PARALYSIS

Paralyses (Gr. \( \text{παράληψις} \)), a solid figure having six faces, the faces being invariably parallelograms, and any two opposite faces equal, similar, and parallel. If the faces are all squares, and consequently equal, the paralleloipied becomes a cube.

Parallels, in military language, are trenches cut in the ground before a fortress, roughly parallel to its defences, for the purpose of giving cover to the besiegers from the guns of the place. See Siege.

Paralysis. The term paralysis, while ordinarily used to express loss of power of movement, is used medically in the wider sense of loss of function, so that there may be paralysis of motion, of sensation, of secretion, &c. The term Paralysis is used to indicate a diminished activity of function. Thus, paresis of a limb means diminished power of moving the limb.

From what has been said under the articles Brain, Nervous System, and Spinal Cord it will be seen that paralysis may arise (1) from destruction of the nerve-cells in the motor area of the surface of the brain; (2) from interruption of the nerve-fibres in their path through the brain to the spinal cord; (3) from interruption of the nerve-fibres in their path through the spinal cord; (4) from disease of the nerve-cells in the spinal cord; (5) from disease or injury to the nerves passing from the spinal cord to the muscles; or (6) from affections of the muscles themselves. Thus, we speak of Cerebral, Spinal, and Peripheral Paralyses.

Cerebral Paralyses.—The most common causes of paralysis from brain disease are the rupture of blood-vessels (see Apoplexy), or the blocking up of blood-vessels with clots, which pass from the surface of the brain by the heart or larger arteries (embolism). Other less frequent causes are tumours, abscesses, &c. The most usual form of paralysis is that termed Hemiplegia, in which there is paralysis of the leg, arm, or muscles of the mouth and tongue, on one side of the body, often accompanied, if the disease is on the right side, by the condition called Aplasia (q.v.). If the original condition has been such as merely to produce pressure upon the nerves without their actual destruction (e.g., pressure of a tumour), the paralysis will be complete and permanent. If this is obviously not very frequent. Hemiplegia may be entirely unaccompanied by any paralysis of sensation, but if the fibres which carry sensory impulses to the surface of the brain be also destroyed there will be a concomitant loss of sensation on the same side as the loss of motion (hemianesthesia). In certain cases, when the disease of the brain is in the pons Varolii, the mouth may be paralysed on the opposite side from the paralysed limbs. (This depends on anatomical considerations.) Destruction by disease of individual ‘motor areas’ will obviously lead to paralysis of the corresponding movements.

Spinal Paralysis is usually the result either (1) of pressure upon the spinal cord from the results of enervation or injury of the spine, or of growths such as tumours or abscesses; (2) of disease of the spinal cord itself, especially from tumours or acute or chronic inflammations, which may lead to interruption of the nerve-fibres which pass downwards from the brain to the nerve-cells in the gray matter of the spinal cord; or (3) of direct injury to the spinal cord itself. If the conducting paths from and to the brain are interrupted in any way, there is complete paralysis of voluntary motion and of sensation below the level of the affected part of the spinal cord, because the motor impulses cannot pass down nor the sensory impulses upwards. At the same time, below the injury reflex movements may be preserved and certain forms even increased. Such spinal paralysis is termed Paraplegia. If the injury to the spinal cord is localised to one side there will be paralysis of the muscles on the same side, supplied by the nerves arising from the cord below the injury, and of sensibility of the opposite side of the body below the injury (see Spinal Cord).

In certain cases the nerve-cells in the anterior horns of the gray matter of the cord (and the same may be said of the corresponding cells of origin of the motor nerves of the brain) may be diseased without implication of any other part of the spinal cord. The result of this is paralysis of the muscles supplied by those nerve-cells, and consequent gradual wasting of the muscles. Under this head come those frequent localised atrophies and paralysis of the children (the so-called ‘essential paralyses’ of children) which affect certain groups of muscles, and lead to such deformities as club-foot and impaired growth of the limbs. A similar disease is met with occasionally in adults (progressive muscular atrophy), which runs a very chronic course and leads to a gradual wasting of muscles, the direct result of a corresponding gradual wasting of the nerve-cells in the gray matter of the cord. The disease called ‘bulbar paralysis,’ in which there is a paralysis of the muscles which control the tongue, of the side of the mouth, and of the larynx, is of this nature, its more rapidly fatal termination being due to the implication of structures so necessary for organic life.

Peripheral Paralyses.—(a) From Affections of Nerves.—These are of extremely frequent occurrence, and may be due to pressure upon, injury to, or disease of the nerves. The most common of these diseases are the inflammations arising from cold, from the excessive use of alcohol, or from exposure to heat or to cold (e.g., frost-bite). Nerves may be affected by a purely motor nerve the resulting paralysis is purely motor. The typical example is the so-called ‘Bell’s’ or ‘facial paralysis,’ from affection of the seventh cranial nerve. This arises most commonly either from exposure to draught or from disease of the ear, in the neighbourhood of which the nerve passes through the bones of the skull (see Ear). There results a complete paralysis of the muscles of expression on the corresponding side of the face; the mouth is twisted to the opposite side, the lips cannot be pursed or retracted, the eye cannot be shut, the head can neither be raised nor depressed, while the usual furrows on the forehead and cheek are either obliterated or diminished. The disease is in many cases amenable to treatment, but when associated with disease of the ear it should always be regarded as of grave import. If proper treatment be neglected, the paralysed muscles may waste, and recovery become impossible. ‘Lead palsy’ is usually indicated by a loss of the power of extending the wrists (wrist-drop) without impairment of sensation (sensory atrophy). Another example of paralysis resulting from pressure on a nerve is seen in the not uncommon result of sleeping with the arms over the back of a chair (sleeping or cratch palsy). As the musculo-spiral nerve is compressed, and the muscles which it supplies—namely, those which extend the wrist and fingers, and which turn the forearm outwards (supination)—are paralysed, there is a wrist-drop like that of lead palsy, but in addition there is loss of sensibility (anesthesia) on the skin of the back of the thumb and first two fingers.

(b) From Disease of Muscles.—A very remarkable form of paralysis—affecting mostly the young—is that termed ‘pseudohypertrophic paralysis,’ in which the onset of the paralysis, which is very gradual, is accompanied by a remarkable apparent overgrowth of the muscles, more especially in the
Parasitic Animals

calves of the legs, in the thighs, and back. Examination of the muscles thus attacked as well as any of the cases above described, may occur without any discoverable lesion. To this term 'hysterical' has been applied (see HYSTERIA). The simulation of organic paralysis by hysteria is frequently so close as to deceive even expert observers. See GOETHE'S theory of physical medicine—Quain's Dictionary of Medicine. For 'general paralysis,' see INSANITY, Vol. VI. p. 155.

Paramaribo, the capital of Dutch Guiana, is situated on the Surinam, about 10 miles from its mouth. It has broad, tree-shaded streets, with clean wooden houses, painted light gray, and numerous canals and churches. There are also a governor's palace, two forts, a park, &c. The Herrnhuters (Moravian Brethren) are a strong body in the town. Except for the small harbour of Nicherie, all the trade of the colony is concentrated at Paramaribo. See statistics under Guiana (Durcut), Pq. (1891), Vol. 48.

Paramatta. See Parramatta.

Paramecium, or Slipper Animalcule, an Infusorium very common in pond water or in vegetable infusions. In shape it is an asymmetrical oval, in length about 1/20 of an inch. If dry grass be steeped in a glass of water for some days, the animalcules dormant on the stems revive and multiply exceedingly. Each paramecium is covered with rows of cilia which lash it through the water and drive food-particles into an aperture which serves as mouth. As the food-particles enter they take bubbles of water with them, and are moved round and round in the living substance until they are digested or got rid of. There are two (excretory) contractile vacuoles; the large nucleus has a small one (paramenon) lying beside it; beneath the thin rind there are remarkable eversible threads. A paramecium often divides transversely into two; these two repeat the process successively till the dividing size is attained, multiplication may thus proceed for a while. It has its limits, however, and then two individual Infusorins conjugate, exchange some of the material of their paramenon, and separate. Thus they seem to renew their youth.

Paraná, (1) an important river of South America, rises as the Rio Grande in the Brazilian state of Minas Geraes, about 100 miles N W. of Rio de Janeiro. It flows north-west and west through and along the southern frontier of Minas Geraes, till it unites with the Paranáhyba. It then receives the river, now Paraná, and turns to the south-west and afterwards to the north, separating Paraná state from Matto Grosso and from Paraguay, round the southern border of which region it sweeps westward to its confluence with the Paraguay River. It then rolls southward through the Argentine provinces, past Santa Fé, below which its channel frequently divides and encloses numerous islands, and finally south-eastward, till it unites with the Uruguay, above Buenos Ayres, to form the Rio de la Plata. The entire length of the river is a little over 2000 miles; it drains an area of more than 1,100,000 sq. m. Its tributaries, besides those already mentioned, are the Mogu Guasen, Tieté, Paranapanema, Ivaity, Iguaçu, and Salado; at San Pedro (38° 40' S. lat.) a delta begins. The principal towns on its banks are Corrientes, Paraná, Santa Fé, and Rosario—all Argentinian. The river is navigable at all times to the influx of the Paraguay (700 miles), and at least water to the mouth of the Iguaçu (460 miles). Immediately above this point occurs one of the most rapid currents in the world. It extends for 100 miles in a straight line up the river, between ranges of crumbling cliffs which confine the stream to a narrow, rocky bed, little more than 100 yards wide. Through this gorge the water pours in tumultuous fury; for above the rapid the river, then 23 miles broad, rushes down over the Salto of Guayra, an inclined plane 55 feet high, and then forces its waters, tossing and churning, into the narrow channel below. (2) A southern state of Brazil, lying opposite Paraguay, 455 sq. m., and a pop. (1888) of 187,548, including several colonies of Germans and Italians. The capital is Curitiba (34,000), with a railway (69 miles) to Paranaguá, the port of the state (pop. 5000). (3) Capital of the Argentinian province of Entre Rios, stands on a high bluff overlooking the Paraná, opposite Santa Fé, 410 miles by steamer from Buenos Ayres. The town was the capital of the Confederation from 1822 to 1861; afterwards it sank rapidly, but has now again a pop. of 15,000.

Parapet (Ital. para-petto, from para 'to protect,' and petto, 'the breast'), a wall raised higher than the gutter of a roof for protection in military works, for defence against missiles from without (see FORTIFICATION); in domestic buildings, wings, churches, &c., to prevent accident by falling from the roof. In classic and medieval architecture balustrades were used as parapets. In early work parapets are generally plain, but in later buildings they are pierced and ornamented with tracery.

Paraphrase (Gr. para, 'beside,' and phrazei, to speak) is the name given to a verbal exposition of something either giving another view of or of a separate passage in it. A paraphrase consequently differs from Metaphrase, or strictly literal translation, in this, that it aims to make the sense of the text clearer by a lucid circumlocution, without actually passing into commentary. The versified marginalia of Scripture forming part of the Psalmsody of the Scottish Church are known as 'the Paraphrases.' See HYMN, Vol. VI. p. 48.

Paraplegia. See PARALYSIS.

Parasite (Gr. from para, 'beside,' sitos, 'food;' one who eats with another; hence one who eats at the expense of another), a common character in the Greek comedies; a low fellow, who is ready to commit to any hint given him to be permitted to partake of a banquet, and who lives as much as possible at the expense of others.

Parasitic Animals are those which live on or in other organisms, from which they derive their food. But this mode of life has many forms and degrees; the hosts may be animals or plants; parasites may be external or internal (ectoparasites or endoparasites), fixed or with the power of movement; they may be parasitic temporarily, for a prolonged period, or for the whole life; restricted to one host, or requiring to pass from one kind of animal to another if the life-cycle is to be completed. For the parasitic animals which infest plants, see COTTON INSECTS, GALLS, &c.; and ASCARIS, FLUCKET, TAPEWORM, THICK-WORMS, TRICHINA, &c., and other parasites are separately discussed.

Grades of Parasitism.—The grades recognised by Leuckart are: (1) Temporary Parasitism.
To this category belong almost exclusively ectoparasites, which differ from their free-living relations only in their diet. (2) Ectoparasites—beings which are invariable limited during a prolonged period or during the whole of the parasitic life. This is called stationery ectoparasitism in the translation of Leuckart's great work, but the term hardly suggests the idea. These parasites either remain throughout all the developmental stages on the host, or at any lead an independent existence under a form more or less different from that of the adult. (3) Endoparasites, in which the parasites are during a great part of their life, and almost invariably during their maturity, boarders within the body of the host. Moreover, all the developmental stages are almost never passed through within one host, a transference from one kind to another being necessary for the completion of the life-cycle. But of endoparasites there are many varieties.

The Hosts of Parasites.—Probably no animals, except some of the simplest, are free from the attacks of parasites. Yet some are more liable than others—e.g. because they offer greater inducements to those parasitically inclined, because they are more accessible, or because they eat infested food. Thus, vertebrates are more abundant than invertebrates, and vermin more than fifty distinct species of parasites, the dog and the ox some two dozen each, the frog perhaps twenty. Some species of parasite are limited to one kind of host; thus, the adults of Bothriocephalus and Cercaeaoni are not known except in man, while Trichina spiralis is found in man, pig, rat, dog, cat, ox, &c., and Distemum hepaticum in many ruminants and other ungulates, in rodents, in the kangaroo, and in man. The systems most infested are the most accessible —parasitic in the alimentary, by ecto- and endo-parasites respectively; but there are no organs in which parasites may not be harboured.

Origin of the Parasitic Habit.—It is probable that most cases of parasitism began gradually. Animals found temporary shelter on or in others, and this might begin fortuitously—e.g. as the embryos or adults wandered or were swallowed; or it might be a shift saving those which adopted it from some presumed keenness in the struggle for existence; or parasitism is the reply of an environment. In many cases, however, we can hardly doubt that the habit began with the natturally more sluggish females, prompted not by hunger, but by the impulse to seek some conveniently sheltered place for the birth of the young. In fact, there are not a few parasitic female Crustaceans whose mates live freely. Of the evolution of parasites from free-living ancestors the free stages still included in the life-history of most, the close relationships between some free and some parasitic members of the same class—e.g. Crustaceans and Nematodes—and the frequent occurrence of temporary parasitism afford sufficient evidence. It is also instructive to consider the three classes of Plathelminthes—Turbellarians (Planarians, &c.), Trematodes (Flukes, &c.), and Cestodes (Tapeworms, &c.)—of whose genetic relationships there seems little doubt; the Turbellarians are almost all free-living; the Trematodes are mostly external, but sometimes internal parasites; the Cestodes are all endoparasites.

Life-history of Endoparasites.—Most endoparasites take part in an eventful life-history. They are not always parasites, or they are not always parasites within the same kind of host. Most of them are at some time free; many of them have some sort of metamorphosis. But, as their life-histories are very various, they do not readily admit of being summed up in general statements.

Let us begin, however, with the adult sexual animals. In this state they are always almost parasitic, partly because rich copious diet, warmth, and the relative ease of the reproductive period. Sexuality is partly because many probably began their parasitic career at the reproductive period, when shelter and readily attained food were specially advantageous; partly because it is not likely that animals which had become parasitic would relinquish this habitat in adults and pass to a reproductive period of some sort. It is also because of some kind of thread-worms (Gordius, Monilis, &c.) and some few insects (ichneumone-flies, gad-flies, &c.) which are parasitic in their youth and free as adults. It is generally true of parasitic animals that the eggs are produced, fertilised, and deposited in the parent stage. The production it should be noted that the fertility is often enormous, for a tape-worm may produce 42,000,000 eggs, and a female thread-worm 64,000,000 in a year; (2) that in some cases where the female alone is parasitic fertilisation may take place before parasitism has begun; (3) that otherwise it occurs within the body of the host; that Trematodes and Cestodes are hermaphroditic and sometimes fertilise themselves; (3) that in tapeworms the fixed 'head' buds off a long chain of joints, each of which finally becomes a sexual reproductive organ; and (4) that some parasitic eggs are often laid in the intestine or on the skin of the host, and grow into embryos, which passively carried along with food and drink into new hosts. There the embryos rarely become or remain quiescent, but wander from the food-canal through the tissues and organs of the host, and then to some extent of its external environment—in other words, a second migration.

But before leaving the so-called intermediate host—which is different from that of the parent or that of the adult—we should notice that within it asexual multiplication may occur. Thus, several asexnal generations characterise that part of a liver-fluke's life during which it sojourns in a water-snail (Lymnaeus) prior to reaching its final or 'definitive' host in the sheep. In other cases, the asexual multiplication within the intermediate host is of a simpler kind, being restricted to budding, as when the bladder-worm or prooecyst of Tenuia echinoccus within ox or man develops many 'heads' or scolecis, each of which on being transferred to dog or wolf will grow into a tape-worm. Or there may be no true multiplication, e.g. in the numerous bladder-worms which form only one head, and remain quiescent until the host happens to be devoured by another, within which the 'head' of the bladder-worm may bud off an adult tape-worm chain.

Connected with this change of host there are two main periods of life—life-history in the snail (1) How is the change effected? (2) how did this extension of the life-history to two distinct hosts arise? In regard to the modes of transmission it will be enough to give two illustrations. The young liver-fluke actively migrates from a water-snail and from the water, encysts on stems of grass, and is then eaten by a sheep.
PARASITIC ANIMALS

Sponges. Ctenostomata. Probably none in strict sense. Very rare instances: Mediushod Oscura (Ctenostoma) parasitic. Oulina (Ctenostoma) octonaria. The Hydrodroid Polypodium hydroides is in one stage parasitic. All parasitic. In another Mediushod, Geryonia proboscis. In the body of the Mediushod Tarritopis. On the ovum of the stolont (Actinophyrurus). Orthonecida (Rhopalura), in a brittle-star (Asterias spp.); in a Neurena worm (Linnaeus levis), Dieyeznide (Vieyeina) in cuttlefish. These forms are perhaps very primitive, perhaps very degenerate, worm-types.

Mollusca. Turbellaria (Planarians, &c.). Trematoda (Flukes, &c.). Cestoda (Tapeworms, &c.). Nemerteans (Ribbedworms, &c.). Nemertina (Thread-worms). Acanthocephala. Mostly free-living; a few genera are parasitic : All parasitic, many externally, and usually on one host. Many internally, and then requiring two hosts. All parasitic; the mature sexual forms in vertebrates, except in the case of Archipterites, which becomes mature in the fresh-water worm Tubifex. Graffilia in marine molluscs. Anophidium in or on Holothurians. Especially on fishes. The first usually a mollusc, the second a second vertebrate. All sorts of vertebrates contain both stages, the adults in the gut, the immature forms usually in the flesh. But the immature stages have also been found in some invertebrates, Arthropods, and worms. Two occur on crabs. In living. The majority in the digestive tract of vertebrates; but they may be transferred from a lower host to a higher—e.g. from insect to mammal. Echinoidea lives as adult in pike, &c., in youth in the amphipod Gammarus pulex; Echinoidea of perch in the snail Acasus. Echinoidea occur in the pig. The minute males of Bonella and Hamangia live within the females. On Crinoids. On molluscs, fishes, amphibians, &c. On crustacean Nebalia. In earthworm and slug.

Echinodermata. None parasitic.

Arthropoda. Crustacea. There are many parasites among Copepods—e.g. Chonodactylus. Calligna. Lernae. Among Clirripedia—e.g. Saccocirra. Among Isopods—e.g. Bopyrus and Echinoperla. The vast majority are free-living, but ectoparasitism is illustrated by Bird-lice (Mallophagas). Lice (Phthiracae). Brosamphora. (Many are parasitic on plants.) Endoparasitism by the larvae of Ichneumon-flies. Gai-flies. The majority are free-living, but parasitism is illustrated by Lingualina (Isopod). By some Acanth (mites). Usually on skin, gills, &c. of fishes. Beneath the tail of crabs. On fishes. \{ Mostly on birds and mammals. In bees and wasps. In other insects. In man, cattle, horses, &c. Embryo in rabbit; adult in frontal sinuses of dog and wolf. Demodex folliculorum, Sarcoptes (itch-mite), in skin of man, &c. With little trace in adult of Acanth appearance.

Mollusca. All free-living, except a few Gastropods. Entoscolex microtila. Eulalia and Stylifer. Within Holothurian Synapta. On or in various Echinoderms. They are said to eat their way into coda and other fishes.

Vertebrata. The haustles (Myxosoma) are the only parasitic vertebrates.

These illustrate (a) many grades of parasitism—temporary, periodic, thoroughly established, and (b) corresponding grades of degeneration. Usually on skin, gills, &c. of fishes. The females only are parasitic, the males free. Precise details are wanting.

The life-histories are often very complex, and may include alternation of generations. Many insect plants. Branchiobdella, which some rank among Clitopods, is parasitic on fresh-water crayfish. This family probably represents Clitopods degenerated by parasitism. In many, however, the ectoparasitism is very temporary.
Here, and in some other cases, the migration is in parasitic animals. On the other hand, a large pig is quite passive in the muscles or connective tissue of that animal, and cannot reach its final host unless 'measly' pork be eaten by man. Here, and in most other cases, the migration is passive. The second problem is very difficult. Is the host or the parasite the initiating agent in the final host, and has that of the immature stages been intercalated? or is the intermediate host really the primitive one in which the animals used to mature, while the final host represents a secondary prolongation of the life-history? Leuckart expressed the second theory that 'the intermediate hosts were originally the true definitive carriers, which formerly brought their intestinal worms to sexual maturity, but have since become merely interme- diate, because the development of the parasites has extended itself over a greater number of stages in the course of further differentia(tion.'

The Environment of Parasites.—It is at present debated (see Heredity) whether the precise in-
fluences exercised on parasites by their hosts are transmissible to the host as the usual absence of sense-organs that the habits and surroundings of parasites have been somehow influential in their evolution. It is certain that individual parasites may vary in different parts of the body and in different hosts, and it is admitted by all that parasites exhibit 'adaptations' to their life and surroundings. It is therefore important to take account of the precise relations between host and parasite. Ectoparasites will experience mechanical influences due to the movements of their bearers, they will often be carried from the locality to which they were sometimes share in the wearing of their hosts, they normally find abundant food, and they are often not only sheltered but sedentary. Endoparasites will experience pressure from the tissues in which they lie, or from the peristaltic movements of the food-canal in which they are lodged; their immediate environment usually involves confined space, scant oxygen, considerable warmth, and total darkness; they will be affected by abundant and rich nutrition, by surrounding gases and juices, and by their frequently sedentary life. Now it is at least a plausible theory that the presence of sense-organs in endoparasites is due to the unstimulating character of the environment, which has caused them to degenerate, and this view is partly con-
firmed by the occasional occurrence of sense-organs in tailing helpels of children, and in that leovomorph appendages are absent or much reduced in the adults of many fixed ectoparasitic crustaceans, because they have gone out of use; that a food-
channel is absent in many endoparasites, partly because the superficial absorption of complex sur-
rounding juices left it functionless; and that the par-
virigy of many is increased by living in surround-
ings in which the respiratory processes must be very sluggish; or that the prolific reproduction— especially perhaps the building growth of tape-
worms— is in part due to the abundant and yet
stimulating nutrition.

Effects of Parasites on their Hosts.—In the 17th and 18th centuries the injurious effects of parasites were much exaggerated. All sorts of diseases, including many which we now know to be asso-
ciated with parasitic infections, were attributed to them. But it can hardly be denied that some
and physicians gravely discussed 'An mors natui-
satis sit substantia vermisur?' As accurate diag-

nosis began to be less unusual, a strange reaction in favour of parasites found many supporters. In-
testinal worms were called 'the good angels of un
willing helpers of children,' and were said to aid digestion and even development. But since the middle of the 19th century, when the experimental study of parasites began in earnest, a knowledge of the various injuries which parasites may do, to man and in domesticated animals at least, has become more and more precise and complete. Only a few illustrations need be given. Numerous large parasites will certainly diminish the nutritive supplies of their host; large bladder-worms and the like press with their influence upon the host's blood-vessels, and give rise to many troubles; the movements and migrations of parasites within the body of the host produce pain and inflammation, and may even result in the perforation and destruction of im-
portant organs. Even external parasites may do considerable damage, as in the case of those which occur beneath the tails of crabs, and some-
times effect the virtual castration of their hosts. On the other hand, there are many less important parasites whose effects are very slight if at all injurious. It is a question of much practical im-
portance how the endoparasites which infest man find their way to their host, but as details will be given in such articles as TAPEWORM and TRICHINA, it is enough here to say that food in which parasites are known to lurk should be in-
spect, cleaned, and cooked. (Note: parasitology.)

Historical.—Most of the ancient and medieval naturalists and physicians who expressed any opinion on such matters believed that parasites were spontaneously generated within the bodies of their hosts. It was not till the 17th century, when Swanmerdaj and Redi showed how maggots, like, & developed from eggs, that the belief in generatio aequivoca began to be seriously disputed. It was gradually replaced by the theory that para-
sites came from without, that, ceasing to be free-
living, they entered the bodies of other animals and were there modified. But this conclusion was too hastily leaped at, and no care was taken to prove that the free-living forms in question did really develop into parasites. In many cases, indeed, it was soon shown that they did not, and this disappointing result helped Pallas and others in the latter part of the 18th century to recognize rightly that parasites were propagated like other animals by means of eggs. They concluded, however, that these eggs were more or less directly carried from one host to another, there to develop. More especially was this true of that idea that the life-history of parasites is rarely so simple; nor was there more than a slight warrant for another favourite idea that young animals inherited parasites from their mothers. At the beginning of the 19th century the helminthologists, such as Rudolphi and Bremer, were very active and greatly extended the list of known parasites, but the life-
histories remained a puzzle, and many naturalists relapsed into a belief in spontaneous generation. The increasing use of the microscope led to most important results: in 1831 Mehlis discovered the
Infusorian-like embryo of certain flies; Von Siebold (1832) detected the six-hooked embryo within the still unliberated ova of the tapeworm; Eschricht (1841) compared the life-history of int-
ernal parasites to that of ichneumon-flies and bot-
tflies; Steenstrup (1842) published his famous essay on alternation of generations; Von Siebold (1843-
50) and Van Beneden (1849-50) worked out the metamorphoses of several parasitic worms; Kien-
meister (1853), Leuckart (1856), and others showed experimental evidence that many worms were transformed into other forms which resulted in the development of adult parasites. The foundations of modern helminthology were thus laid, and we have now a vastly increased knowledge of the number of parasites, a precise acquaintance with the life-histories of some of the most important, a scientific system of medical diagnosis and treatment, and some realisation of the general biology of parasitism.
PARASITIC DISEASES

PARASITIC DISEASES constitute an important sub-group in the accepted classification of Disease (q.v.). In these diseases certain morbid conditions are induced by the presence of animals or vegetable parasites which have found a place of subsistence within some tissue or organ, or upon some surface of the body of man or other animals. Plants also have partaken of this nature (see PARASITIC PLANTS). The forms of animal life giving rise to parasitic diseases are described in articles on Ascaris, Cestoid Worms, Flies, Guinea-worm, Ichneumon, Lice, Nematodaria, Strongylias, Tapeworms, Ticks, etc.

The vegetable organisms which are associated with special diseases are almost all of microscopic size, and therefore, though their effects are of much greater importance than those of animal parasites, they are as yet much less perfectly understood. Certain minute fungi have long been recognised as the causes of diseases in the skin and mucous membranes: Ficus, Pityriasis versicolor, Ringworm, Trachoma (q.v.). It was shown in 1861 by Carter that a serious disease of the foot which occurs in India (Mauloon-foot, fungus-foot, &c.) is due to the presence of a fungus, and in 1877 what is now called Actinomycosis (q.v.) was put in the same category.

But the most important and interesting of the vegetable parasites are those belonging to the Schizomycetes or Bacterium (q.v.). Some classes of these organisms to their host are much more intimate than in the case of the larger parasites, and the problems presented by the diseases associated with them are consequently much more difficult of solution; but in some cases the parasitic nature of these diseases has been completely established. Analogy makes it probable that some day all specific feline diseases will have to be included in this group. See GERM THEORY.

PARASITIC PLANTS are those which, unable to nourish themselves, prey upon other plants or animals; becoming attached, they gain access to the tissues of their host and feed upon its juices. They are more or less degenerate, according to the extent of their parasitism. Any climbing plant is so far a parasite, but, not drawing any nourishment from its host, merely using it as a support, it can live without it, and is perfect in all its parts. Many parasites have probably developed from such plants. The mistletoe, on the other hand, has no roots in the ground; its seed is left by a bird upon an apple or an oak tree, to which, when it begins to grow, it becomes attached by means of special organs called haustoria, which act as roots and draw sap from the host, together with carbonic acid from the air, and elaborate food for its tissues. In the ease of the dodder, again, which begins life as an independent plant, the seed germinates underground; when the young plant has reached a certain stage of development it fastens upon some host, twining round it, sending its haustoria deep into the tissues, and drawing all its nourishment from them: it bears no green leaves, but only flowers, while the part in the ground dies. In the Rafflesiaaceae, a foreign order, remarkable for the size of the flowers of some of its genera, the degradation has gone still further, and the young plant consists of a knob-like mass of tissue half formed by the host, and the flowers. There are some parasites which are attached to the roots instead of the stems of their hosts—e.g. Yellow Rattle, Cow-wheat, Eyebright. The attachment by the haustoria is always remarkable; the only influence of the host is always joined to the corresponding ones of the host, often in such a way that it is difficult to say to which plant they belong. The ovules of many parasites are rudimentary, the embryo is small and without chlorophyll; in cases of advanced parasitism it may even produce no leaves. There are parasitic genera in many orders—e.g. Corallorhiza in the Orchideae, Casuca in Convulvulaceae, Ovulaire in Labiatae, Monotropa in Pyrolaceae. The Loranthaceae, of which is Viscum the mistletoe, the Balanophorea, and the Santalaceae are families of doubtful affinity. Nearly all these parasites have a marked preference for a particular species of host, and they are all flowering plants. But there are many others; two whole classes, the Bacteria and the Fungi, are either parasitic or, what is much the same thing, saprophytic—the latter upon decaying organic matter for food. The Bacteria have animals as their hosts, and cause in them many diseases, the species being often recognised by the disease. When they are saprophytic they cause fermentation and putrefaction. The Fungi are many of them a trouble in agriculture, causing corn rust; potato disease (see PLANTS, DISEASES OF), and also salmon disease; others, like the mushroom, are saprophytes. Allied to parasitism is Symbiosis (q.v.), a sort of mutually arranged parasitism for the benefit of both parties; as in the case of the Lichens, which consist of Algae and Fungi in partnership.

Paratoluidin. See TOLUIDIN.

Paray-le-Monial. a town in the French department of Saône-et-Loire, 48 miles by rail W. by N. of Mâcon, celebrated for its chapel, in which Mary Alacoque (d. 1690) believed herself to have had a vision of the Saviour, now the object of pilgrimages by the confraternities of the Sacred Heart (q.v.). Pop. 3269.

Parce. See FATE.

Parchim. a town of Mecklenburg-Schwerin, 23 miles S.E. of Schwerin. Pop. 9726.

Parchemin (Fr. parchemin, Lat. pergamenum, through Gr. from Pergamus). At a very early period the skins of animals were used for writing upon. Some authors who have written on the subject of ancient writing materials think that the king of Pergamos brought the art of making parchment to perfection through Ptolemy Epiphanes having prohibited the exportation of papyrus from Egypt. The skins were then prepared, paper was made, and this practice was continued in Italy till about the 10th century, but parchment was also used; and from that time till ordinary paper became available in the 14th century parchment was almost the only material employed (see PALEOGRAPHY, PAPER). To a limited extent smaller plates were written upon as late as the 14th and 15th centuries, and some of these are preserved at Florence. Some of the earliest printed books were done on vellum (a name originally given to a parchment made of calf-skin), and a great deal of weighty writing is done in vellum from the skins of calves prematurely born, some of the best of the early miniature portraits were painted. Ordinary parchment is chiefly made of sheep-skins, but those of calves and goats are
also used. Fine parchment and vellum are prepared from the skins of kids, lambs, and young calves. A coarser parchment for drumheads, tambourines, &c. is manufactured from the skins of male goats, and canvas or burlap is used for sacks. A kind is made from asses' skin, and for bookbinders' use a parchment is sometimes prepared from pig skin. The early stages in the manufacture of parchment are the same as for leather (q.v.). After being unhaired and cleaned, the skins are stretched over a frame or wooden frame called a roll. The flesh side of the skin is first gone over with a double-edged semicircular knife (fleshing-tool) to remove adhering particles of flesh. With the fleshing-tool inverted, to prevent any cutting of the epidermis, the other side of the skin is then scraped to remove dirt and to squeeze out some of the absorbed water. For some purposes for which stout parchment is required, the skin is now merely allowed to dry on the frame, no further treatment being required. But fine parchment for writing or drawing upon, some of which is made from split skins, is sprinkled with sifted chalk on the flesh side and rubbed smooth with a flat surface of pumice-stone. The grain side of the skin also is rubbed over with pumice, but no chalk is used. In these operations great care is required to be taken not to fray them, for injured portions become necrotic during the drying of the parchment. Any considerable roughness or unequal thickness is removed by the skin being again scraped and pumiced.

Vegetable Parchment.—This substance, which excited much interest and curiosity when it was first introduced, was patented by Mr. W. E. Gaine in 1833 (no. of specification, 2834). It is made by dipping ordinary unsized paper for a few seconds in concentrated sulphuric acid mixed with one-half its volume of water, and then quickly removing all trace of the acid. The mixture is allowed to cool before being used. This simple treatment produces a remarkable change in the paper. It acquires a parchment-like texture; turns translucent, especially when thin; and becomes about five times stronger than ordinary paper. Vegetable parchment are impervious to water, but is rendered soft and limp when dipped into it. The acid produces a molecular change in the Cellulose (q.v.) of which paper consists. A solution of chloride of zinc acts on paper in a similar way. The mixture, or paper, is made by pouring a solution of zinc chloride into a bath and heating, a bath being produced from the reactions of the action of the solution and the paper. The paper is then washed free from the zinc chloride and dried, but the zinc is not removed from the paper and is left on the surface. This process is repeated several times until the paper is sufficiently free from the zinc chloride. The paper is then dried in a drying oven and then rolled up in rolls, which are then wrapped in a paper bag and stored in a dry place. Vegetable parchment have been used for book-covers and for writing deeds upon. Thin sheets of it serve as a convenient material for tracing designs, plans, &c.

Pardoe, JULIA, born at Beverley in 1806, published poems and a novel in her fifteenth year, and Traits and Traditions of Portugal in 1833. A visit to Constantinople in 1836 led to her City of the Sultan, Romanin, and an account of the Bosphorus. She next visited Hungary, and wrote The City of the Magyar, and a novel, The Hungarian Castle (1842). A series of works deal with French history—Louis XIV. and the Court of France (1847), The Court and Reign of Napoleon (1849; new ed. 1850), A Pilgrimage in Paris, and Episodes of French History (1859). Others of her numerous works are The Confessions of a Pretty Woman, Flies in Amber, The Jealous Wife, Reynold Lyle, Lady Arabella, and The Thousand and One Days. She received a pension of £100 in 1859, and died 28th November 1892.

Pardon, in Law, is the remission of the penalty inflicted on an offender who has been tried and convicted, and the discharge of guilt and retribution which has been regarded as the prerequisite of the sovereign; in England a law of 1536 (Henry VIII.1) expressly denies to any other than the king the power to pardon or remit treasons or felonies. In republican countries the people is sovereign, but the pardoning power is usually delegated to the head of the executive government for the time being. The United States constitution gives the power to the president to grant reprieves or pardons for offences against the United States, except in cases of impeachment; and in all but six states the legislature, or the Union the same power is conferred on the governor. In Florida the pardoning power is vested in the governor, the justices of the supreme court, and attorney-general, or a major part of them; in Louisiana the governor pardons only on the recommendation of the attorney-general, and the presiding judge of the court which tried the case—but only the general assembly may pardon in cases of impeachment and treason; in New Hampshire and Vermont the governor exercises the power with the aid of the executive council; and in New Jersey, Ohio, and Pennsylvania there are boards of pardons—in New Jersey the board consists of the governor, the chancellor, and six judges of the court of errors and appeals. In Britain pardon may also be granted by the supreme authority of the House of Commons; Acts of Indemnity (q.v.) are practically grants of pardon. The sovereign's power of pardon is at all times limited. Thus, he cannot pardon certain offences specified by law (21 Geo. III. chap. 49, excludes the power to pardon convicted of Sabbath-breaking); the king cannot pardon in a matter of private, as opposed to public, wrong, though fines may be remitted in such cases. The endurance of the penalty is said to work out a constructive pardon; and the effect of the pardon is to put the offender legally in the position of an innocent man, so that he may proceed at law against any one who thereafter calls him traitor or felon. But civil rights are not overridden by pardon; the injured person may recover damages from a pardoned offender. In modern times the crown's prerogative is delegated, the crown acting not personally but on the representation of the home secretary, the secretary for Scotland, and the lord-lieutenant in Ireland. The pardon is by warrant under the Great Seal, or under the sign-manual. To those who have been unjustly convicted, their innocence being subsequently proved, not merely is a free pardon granted, but compensation may also be allowed (see IMPERNONIMENT). In a noble case cited, and is an act of grace rather than condemnation is that of the Earl of Dunleith (q.v.). See also Indulgence.

Pardubitz, a town of Bohemia, on the left bank of the Elbe, 55 miles by rail E. of Prague, has a fine 16th-century castle. Pop. 10,292.

Paré, AMBROISE, the father of modern surgery, was born about the beginning of the 16th century, at Laval, in the French department of Mayenne, was trained at the Hôtel-Dieu of Paris, and in
1538 as surgeon joined the army starting for Italy. In a later campaign he improved the mode of treatment of gunshot wounds, which had up to this time been of the most barbarous kind—namely, cannibalisation with boiling oil. It was during this campaign that he substituted ligature of the arteries for the amputation of an artery or an amputation of a limb. Many other important improvements in surgery were introduced by him at this time. In September 1532 he was appointed surgeon to King Henry II, and afterwards to Charles IX. and Henry III. He died at Paris, December 22, 1590. His works, which the child of Paré's, "Chirurgie de Chirurgie" (1562), have exercised a great influence on the practice of surgery in all countries. See Stephen Pueg, Ambroise Pare and his Times (1897).

Paregoric, or Paregoric Elixir (from the Gr. paragoricos, 'soothing'), the Compound Tincture of Camphor of the British Pharmacopoeia, consists of an alcoholic solution of opium, benzoe acid, camphor, and oil of anise, every fluid ounce containing 2 grains each of opium and benzoe acid, and 1/2 grains of camphor. This preparation is much used both by the profession and the public. In dose as low as from 30 to 60 drops it is an excellent remedy for hemorrhage of old people; the opium diminishing the bronchial secretion and the sensibility of the pulmonary mucous membrane, while the benzoe acid and oil of anise act as stimulating expectorants. It has also been found useful in chronic rheumatism, and, especially in the case of children, to relieve slight pains in the stomach and bowels.

Pareira-Brava, a lofty climbing shrub inhabiting the forests of Peru and Brazil, which bears bunches of oval berries resembling grapes. The botanical source was for some time obscure, but it is now known that the plant yielding the root of commerce is the Chondodendron tomentosum (Ox. Menispermeae). The plant has a long branching woody root, of a yellowish to greenish brown colour internally, and this has attained considerable reputation in medicine. The root contains a bitter principle, and is used in chronic catarrhal affections of the bladder and in calculus. The decoction and fluid extract are most usually employed, but it is sometimes given in the simple form of powder. This medicinal root has been recommended erroneously, also to the allied Cissampelos pareira, a climbing shrub of the West Indies and Mexico, and to the Botryopsis platyphylia—both of which plants have roots possessing similar properties.

Parella, a name given to some of those erasmosceous rhizomes which are used to produce Archil, Cardiram, and Litmus, but which more strictly belongs to one species, Leucozia parella, and the red or crimson dye prepared from it.

Parenychyma, a technical name for that kind of vegetable tissue in which the component cells are roundish or polyhedral, touching each other by their broad faces, forming more or less closely, as in the green 'palisade-parenchyma' of the upper part of a leaf, or leaving wide intercellular spaces, as in the 'spongy parenchyma' of the lower part. See Cell, Leaf.

Parent and Child. The legal relation between parent and child is one of the incidents or consequences of the relation of husband and wife, and flows from the contract of marriage. The legal is to be distinguished from the natural relation, for two persons may be by the law of nature parent and child, while they are not legally or legitimately so. Hence a radical distinction exists between natural or illegitimate and legitimate children, and their legal rights as against their parents respectively are very different. Legitimate children are the children of two parents who are recognised as married according to the laws of the country in which they are domiciled at the time of the birth; and, according to the law of England, if a child is illegitimate at the time of the birth, nothing that can happen afterwards will ever make the child legitimate. Hence illegitimate always illegitimate.' In Scotland, on the other hand, a child born of parents who were not married at the time of the birth is made legitimate by their subsequent intermarriage. For a statement of the law relating to illegitimate children, see the article ILLEGITIMACY, LEGITIMATION, and see also FAMILY, INFANT.

As regards the maintenance of the child, it is somewhat singular that, according to the law of England, there is no duty whatever on the parent to support the child, and consequently no mode of enforcing such maintenance. The law of nature was probably considered sufficient to supply the motives which urge a parent to support the child, but the municipal law of England has not made this duty compulsory. This defect was to some extent remedied when the Poor Law was created by statute in 1834. It is now the rule of law that parents and children are compellable to a certain small extent, but only when they have the pecuniary means to do so, to support each other, or rather to help the parish authorities to do so. But apart from the poor-law statutes there is no legal obligation on the parent to support the child, nor on the child to support the parent. Hence it follows that, if the child is found in a destitute state, and is taken up, fed, clothed, and saved from starvation by a stranger, it is questionable whether such a stranger can sue the parent for the expense, or any part of it. Of course, the stranger has a moral and a legal right to demand recompense. In order to make the father liable for maintenance there must in all cases be made out against him some contract, express or implied, by which he undertook to pay for such expenses; in other words, the mere relationship between the parent and child is not of itself a ground of liability. But when the child is living in the father's house, it is always held by a jury or court that slight evidence is sufficient of, at least, an implied promise by the father to pay for such expenses. For example, if the child order clothes or provisions, and are either seen or heard of by persons of consumption, it will be taken that he assented to and adopted the contract, and so will be bound to pay for them. So, if a parent put a child to a boarding-school, very slight evidence of a contract will be held sufficient to fix him with liability. Nevertheless, in strictness of law, it is as necessary to prove a contract or agreement on the part of the parent to pay for these expenses as it is to fix him with liability in respect of any other matter. If a child be put under the care and dominion of an adult person, and the latter neglect or refuse to feed or maintain such child, where the child dies or is injured, such adult will incur the penalties of misdeemour; but this offence does not result from the relationship of parent and child; it may arise between an adult and child in any circumstances, with a person who acts as a master, or as an apprentice or servant. If a parent runs away and deserts his children, leaving them destitute and a burden on the parish, the overseers are entitled to seize and sell his goods, if any, for the benefit and maintenance of such children; and if the parent so deserting the child work or other means to support them, such parent may be committed to prison as a rogue and vagabond. Not only, therefore, is a parent during life not bound to maintain his or her child (with the above exceptions), but after the parent's death the executors or other representatives of the parent, though in possession of
PARIS, the capital of France, and the largest city in Europe after London, is situated in 48° 50' N. lat. and 2° 20' E. long., on the river Seine, about 110 miles from its mouth. It lies in the midst of the plain of the Île-de-France, at a point to which converge the chief tributaries of the river, the Yonne, the Marne, and the Oise. These streams, navigable for the small vessels formerly used in commerce, gave it until recent times the advantages of a seaport, while the great trade routes passing along their valleys connected it with all parts of France. It is still the centre of a great network of rivers, canals, roads, and railways; hence its commercial importance. Paris has occupied since Roman times a constantly increasing series of concentric circles. The present city is bounded by fortifications—a rampart upwards of 22 miles in length, begun in 1840 and completed twenty years afterwards. The extension of the city boundary to this line explains the increase of population from 1,174,346 in 1856 to 1,636,745 in 1866; and from this to 1,825,274 (1881) 2,209,023; and (1891) 2,447,957. Paris has within the fortifications a mean elevation of about 120 feet, but it rises in low hills north of the Seine, Montmartre (400 feet) and Belleville (320 feet), and south of the Seine, the Montagne Sainte-Geneviève (1360) which derives its elevations are encircled at a distance of from two to five miles by an outer range of heights, including Villejuif, Meudon, St. Cloud, and Mont-Valerien (650 feet), the highest point in the immediate vicinity of the city. The Seine, which enters Paris in the south-east at Bercy, and leaves it at Passy in the west, divides the city into two parts, and forms the two islands of La Cité and St. Louis, which are both covered with buildings.

France has long been the most highly centralised country in Europe, and Paris as its heart contains a great population of government functionaries. Paris is a city of pleasure, and attracts the wealthy from all parts of the world. These wealthy inhabitants make it a city of capitalists and a great manufacturing centre. The great universities of France have been deprived of their attraction by the schools of Paris, to which flock the youth of France. The publishing trade has followed the same course. Paris cannot be described as a manufacturing town. Its chief and peculiar industries produce articles which derive their value not from the cost of the material,

funds, are also not bound. It is true that if the parent die intestate both the real and personal property will go to the children, but the natural parent is entitled, if he choose, to disinherit the children, and give away all his property to strangers, provided he execute his will in due form, which he may competently do on death-bed if in possession of his faculties.

A father has the right to the custody of his child until majority at least, as against third parties, and no court will deprive him of such custody except on strong grounds. Whenever the child is entitled to property, the court so far controls the parent in the father's regard as to not deal with cruelty, or to be guilty of immorality, a guardian will be appointed. The court has often to decide in cases of children brought before it by habeas corpus, when parties have had the custody against the father's will. In such cases, if the child is under fifteen, the court cannot declare the parent illegal, and the child is not shown to be cruel or immoral, the court will order the child to be delivered up to him; but if the child is above fourteen, or, as some say, above sixteen, the court will allow the child to remain with the mother. If the parents separate by agreement, no stipulation will be enforced prejudicial to the child. In case of divorce or judicial separation the Court of Divorce has power to direct who is to have the custody of the children. The law lays upon fathers the duty of providing for their children as much as they can, by the purchase of food, reading, writing, and arithmetic; and a father has the right, which the court will not interfere with except on special grounds, to have his children educated in his own religious faith.

Scotland.—The law of parent and child in Scotland differs in some respects from the law of England and Ireland. In Scotland there is a legal obligation on parents and children to maintain each other if able to do so, and either may sue the other for alimony at common law; but this obligation extends only to that which may be called subsistence money, and not to the help which the child requires to purchase his education, and to have his health attended to. The legal liability as between parent and child is qualified in this way by the common law, that if a person has both a father and a child living and able to support him, then the child is primarily liable, and next the grandchild, after whom comes the father, and next the grandfather. Not only are parent and child liable to support each other while the party supporting is alive, but if he dies his executors are also liable; and this liability is not limited by the age of majority, but continues during the life of the party supported. Another advantage which a Scotch child has over an English child is that the father cannot disinherit it—at least so far as concerns his movable property (see LEGITIM). With regard to the custody of children in Scotland, the rule is that the father is entitled to the custody as between him and the mother. His right, however, is not absolute, but subject to the equitable jurisdiction of the Court of Session, which makes such orders regarding custody as are dictated by a regard for the health, interests, and moral education of the child. In actions for separation or divorce this court has power to make such orders as are just and proper regarding the custody of the children of the spouses.

By the Guardianship of Infants Act, 1888, infant is defined as a child under the age of one. The general effect of the enactment is to place the mother of children whose father is dead in a similar position to that which the father would have occupied had he been alive in regard to the guardianship.

United States.—The American law closely follows that of England on this head, save in regard to the age (usually eighteen) at which women cease to be infants. See INFANT, AGE.

Parhelion. See HALOS.

Pariahs is the Tamil name now generally given to the lowest class of the Hindu population of Southern India. They do not belong to any of the four castes of the Brahminical system (the Telugu name is Malga, the Kanarese Koba, the Malayalam Padiyar). In the Madras Presidency they numbered, in 1851, 4,439,253, or 15.8% per cent. of the total population, or four times as numerous as the Brahmins. Presumably they represent the aboriginal race conquered by the Sudras, themselves a stock vanquished by the Vedic peoples. In the 18th century Pariahs were slaves to the higher castes; they must still dwell in huts outside the village bounds, but are frugal, pleasure-loving, and laborious. See CASTE.—For the Pariah Dog, see DOG.

PARIS, the capital of France, and the largest city in Europe after London, is situated in 48° 50' N. lat. and 2° 20' E. long., on the river Seine, about 110 miles from its mouth. It lies in the midst of the plain of the Île-de-France, at a point to which converge the chief tributaries of the river, the Yonne, the Marne, and the Oise. These streams, navigable for the small vessels formerly used in commerce, gave it until recent times the advantages of a seaport, while the great trade routes passing along their valleys connected it with all parts of France. It is still the centre of a great network of rivers, canals, roads, and railways; hence its commercial importance. Paris has occupied since Roman times a constantly increasing series of concentric circles. The present city is bounded by fortifications—a rampart upwards of 22 miles in length, begun in 1840 and completed twenty years afterwards. The extension of the city boundary to this line explains the increase of population from 1,174,346 in 1856 to 1,636,745 in 1866; and from this to 1,825,274 (1881) 2,209,023; and (1891) 2,447,957. Paris has within the fortifications a mean elevation of about 120 feet, but it rises in low hills north of the Seine, Montmartre (400 feet) and Belleville (320 feet), and south of the Seine, the Montagne Sainte-Geneviève (1360) which derives its elevations are encircled at a distance of from two to five miles by an outer range of heights, including Villejuif, Meudon, St. Cloud, and Mont-Valerien (650 feet), the highest point in the immediate vicinity of the city. The Seine, which enters Paris in the south-east at Bercy, and leaves it at Passy in the west, divides the city into two parts, and forms the two islands of La Cité and St. Louis, which are both covered with buildings.

France has long been the most highly centralised country in Europe, and Paris as its heart contains a great population of government functionaries. Paris is a city of pleasure, and attracts the wealthy from all parts of the world. These wealthy inhabitants make it a city of capitalists and a great manufacturing centre. The great universities of France have been deprived of their attraction by the schools of Paris, to which flock the youth of France. The publishing trade has followed the same course. Paris cannot be described as a manufacturing town. Its chief and peculiar industries produce articles which derive their value not from the cost of the material,
but from the skill and taste bestowed on them by individual workmen. They include jewellery, bronzes, artistic furniture, and decorative articles known as 'articles de Paris.' In consequence of the intelligence and taste required in their trades, the Paris workmen are in every respect superior to the machinists of manufacturing cities. The absence of extreme poverty among them and their well-to-do appearance strike the English visitor.

Before speaking in detail of the streets, boulevards, and places or squares of Paris, it is proper to mention that the private houses as well as the public buildings are built of a light-coloured limestone, quarried in the neighbourhood of the city, easily cut with the saw and carved ornamentally with the chisel. With this material they are reared in large blocks to a height of six or seven stories, each floor constituting a distinct dwelling; access to all the floors in a tenement being gained by a common stair, which is usually placed under the charge of a porter or concierge at the entrance. Very frequently the tenements surround an open quadrangle, to which there is a spacious entry, the gate of which (the porte cochère)

is kept by a porter for the whole inhabitants of the several stairs. In these respects, therefore, Paris differs entirely from London; for instead of extending rows of small brick buildings of a temporary kind over vast spaces, the plan consists of piling durable houses on the top of each other, and confining the population to a comparatively limited area. In the great new streets which were formed in the time of the Emperor Napoleon III. this general plan has been adhered to, but with this difference, that instead of being narrow and crooked they are wide and straight. Among the finest are the Rue de Rivoli, two miles in length, the Rue de la Paix, the Rue du Faubourg St Honoré, and the Rue Royale. The Boulevards, which extend in a semicircular line on the right side of the Seine, between the nucleus of the city and its surrounding quarters, present the most striking feature of Paris life. In all the better parts of the city they are lined with trees, seats, statues, kiosques, and little towers, covered with advertisements. Restaurants, cafés, shops, and various places of amusement succeed one another for miles, their character varying from the height of luxury and elegance in the western Boulevard des Italiens to the homely simplicity of the eastern Boulevards Beaumarchais and St Denis. Among the public squares or places the most noteworthy is the Place de la Concorde, which connects the Gardens of the Tuileries with the Champs-Élysées, and embraces a magnificent view of some of the finest buildings and gardens of Paris. In the centre is the famous obelisk of Luxor, covered over its entire height of 73 feet with hieroglyphics. It was brought from Egypt to France, and in 1836 placed where it now stands. On the site of this obelisk stood the revolutionary guillotine, at which perished Louis XVI., Marie Antoinette, Philippe Egalité, Charlotte Corday, Danton, and Robespierre. Of the other squares the following are some of the finest: the Place du Carrousel, including the site of the Tuileries burned by the Commune and not restored; the Place Vendôme, with Napoleon's Column of Victory; the Place de la Bastille, where once stood
that famous prison and fortress; the Place Royale, with its two fountains and a statue of Louis XIII.; the Place de l'Hôtel de Ville, formerly Place de la Grève where their incomparable public executions. Triumphal arches are a feature in the architecture of Paris. The Porte St Martin and Porte St Denis were erected by Louis XIV. to commemorate his victories in the Low Countries, and are adorned with bas-reliefs representing events of these campaigns; the Arc de Triomphe de l'Étoile was begun by Napoleon in 1806, and completed in 1836 at a cost of more than £400,000. This arch, which bounds the Champs-Élysées, has a total height of 152 feet and a breadth of 137. It is profusely adorned with statues and bas-reliefs, some of which, representing the departure and return of the Grande Armée, are masterpieces of sculpture. The great streets which radiate from the Arc de Triomphe were among the most magnificent of those constructed by Napoleon III., and make this monument of the Bonaparte family the most conspicuous in Paris. A great avenue runs east from it to the Palace of the Louvre, in the heart of the city.

The Seine in passing through Paris is spanned by twenty-eight bridges. The most celebrated and ancient are the Pont Notre Dame, erected in 1500, and the Pont-Neuf, begun in 1578, completed by Henri IV. in 1604. This bridge, which crosses the Seine at the north of the Île-de-la-Cité, is built on twelve arches, and abuts near the middle on a small peninsula, jutting out into the river, and planted with trees, that form a background to the statue of Henri IV. on horseback placed in the central open space on the bridge. The bridges all communicate directly with spacious quays, planted with trees, which line both banks of the Seine, and which, together with the Boulevards, give special characteristic beauty to the city. During the last two centuries of the ‘ancien régime’ the Pont-Neuf was the centre of Paris. It was a meeting-place of showmen and charlatans, and there popular orators addressed the mob. Early in the 12th century Ogival or Gothic architecture took its rise in Paris, or the district immediately surrounding it, this event being one of the most memorable in the history of art. Unfortunately the Parisians, with an impatience of everything not in the latest fashion, long neglected their old buildings in the style they had originated. Their Gothic churches were disfigured by incongruous additions and tawdry ornaments, which made them uninteresting if not repulsive to visitors. This remark, however, does not apply to the first two churches we shall mention. They have been admirably restored, and it is now difficult to say whether their incomparable beauty is to be more attributed to mediaeval builders or to the modern architects by whom they have been renovated.

Among the parish churches of Paris (upwards of sixty in number) the grandest and most interesting, from both historical and architectural points of view, is the cathedral of Notre Dame, which stands on a site successively occupied by a pagan temple and a Christian basilica of the time of the Merovingian kings. The main building, begun in the 12th century, is 400 feet long, 150 feet wide, and 110 high. The height of two towers is 218 feet, that of the flèche 300 feet. The interior consists of a principal and two flanking naves, which are continued round the choir. It has been said that if the pillars of Notre Dame could speak they might tell the whole history of France. The kings, however, were crowned at Rheims, and the only royal coronation celebrated at Notre Dame was that of Henry VI. of England in 1431. There, too, was sung in 1436 a memorable Te Deum when Paris was retaken by the troops of Charles VII. During the French Revolution the church was mutilated in order to destroy what were supposed erroneously to be emblems of royalty. In 1793, after childish and revolting merrymakers of the ceremonies of the Roman Catholic Church, it was converted into a temple of reason.’ In 1804 Napoleon I. at the height of his power resolved to impress Europe by an imposing ceremony—that of his coronation—in Notre Dame; and there it was that he, in presence of the pope, who never before had crossed the Alps at the bidding of king or emperor, rudely placed the crown upon his own head. In 1831 the novel of Victor Hugo, Notre Dame, made the church interesting to all Europe. In France there was a general desire for its restoration, and in 1845 this great work was undertaken by the state. Viollet-le-Duc added to the building the great flèche, a structure of oak and lead; and under the care of some of the ablest architects of France the church was converted into what is now described in Paris as the noblest of Gothic buildings. The Sainte Chapelle, built by St Louis in 1245-48, for the reception of the various relics which he had brought from the Holy Land, is perhaps the greatest existing masterpiece of Gothic art. Restored by Napoleon III. at a cost of £50,000, it was threatened by the Commune, but saved. One of the most interesting churches in Paris is St Séverin, buried in narrow streets of the Quartier Latin. A large part of it is in the English Gothic of the 15th century, showing that it was erected during the English occupation of Paris. St-Germain-des-Prés, which is probably the most ancient church in Paris, was completed in 1163; St Etienne du Mont and St Germain l'Auxerrois, both ancient, are interesting—the former for its picturesque and quaint decorations, and for containing the tomb of St Geneviève (q.v.), the patron saint of Paris; and the latter for its...
rich decorations and the frescoed portal, restored at the wish of Margaret of Valois. Among modern churches is the Madeleine (1806-1842), built in the style of a Corinthian temple, and originally intended by Napoleon I. to be a monument to the Grande Armée. It forms an oblong building, 325 feet long by 183 wide, independently of the flights of steps on the façade of 62 feet, that of the entablature 14 feet, and the entire height from the ground 116 feet. There are in all fifty-two columns. The roof is of iron and copper. The interior is elaborately decorated with gold, white marble, paintings, and sculptures; but in some respects this building is a peculiar creation of the architect. The Panthéon (1764) was begun as a church, but converted by the Constituent Assembly of republican France into a temple dedicated to the great men of the nation, restored to the church by Napoleon III. and rededicated to St Genevieve, but once more, on the occasion of the funeral of Victor Hugo (1885), reconverted into a monument, with the old inscription 'Aux grands hommes en patrie reconnaissante.' The Panthéon of Rome and St Paul's in London. The frescoes of the interior are very fine. In the crypt are the tombs of Voltaire, Rousseau, and Victor Hugo. Notre Dame de Lorette, erected in 1823, is a flagrant specimen of the meretricious taste of the 19th century, and St Paul, completed in 1844, is somewhat less gaudy and more imposing in style. Among the few Protestant churches, l'Oratoire is the largest and the best known. For the great church of Sacré Cœur at Montmartre, see SACRED HEART.

The Château de Fontainebleau is one of the most important places of amusement suited to the tastes and means of every class, including over forty theatres. The leading houses are the Opéra, the Théâtre Français (chiefly devoted to classical French drama); it was burned down in 1900, the Opéra Comique, and the Odéon, which are assisted by the Théâtre des Arts. The new opera house (1875) is one of the most magnificent buildings of this century, costing, exclusive of the site, £1,290,000. Cheap concerts, equestrian performances, and public balls, held in the open air in summer, supply a counterpoint to the fifty or twenty working classes at a moderate cost, and form a characteristic feature of Paris life; while, in addition to the noble gardens of the various imperial palaces, the most densely-crowded parts of the city have public gardens, shaded by trees and adorned with fountains, in which the people may obtain health and recreation to the poor. Beyond the fortifications at the west of Paris is the Bois de Boulogne, converted by Napoleon III. from a wooded country into one of the most beautiful gardens in Europe. It takes the place of the London parks for the fashionable world of Paris. East of Paris is the Bois de Vincennes, an admirable recreation ground for the working-classes.

Paris has three large and twelve lesser cemeteries, of which the principal one is Père-la-Chaise (see LACASSINE), covering 456 acres, and filled in every part with monuments erected to the memory of the countless number of celebrated persons buried there. The Morgue (q.v.) at the upper end of the Ille-de-la-Cité is a building in which the bodies of unknown persons found in the Seine are placed temporarily for recognition. The southern parts of Paris are built over beds of limestone, which have been so extensively quarried as to have become a network of vast caverns. These quarries were first converted in 1784 into catacombs, in which are deposited the bones of the dead, collected from the ancient cemeteries of Paris.

It has been frequently remarked that Paris contains few important civil buildings of the middle ages, which is to some extent due to the reckless way in which improvements have been carried out. What Paris has lost in picturesque interest and architectural variety from this cause was brought home to all by the large imitations of the Théâtre Francais and the Palais-Royal, which is 62 by 121 feet, and of the Gare du Nord of 1889. A government commission now watches over the historic monuments of Paris, so that further destruction is checked. Two most interesting civil buildings of the 13th century still exist. One is the Hôtel de Cluny (see CLUNY), the other the Hôtel de Sens, the ancient residence of the bishops of Sens, and most beautiful of the old palaces of the French archbishops of Sens, formerly metropolitans of Paris. It is unfortunately buried among narrow streets north of the Seine and opposite the Cité. In 1806 its most interesting part was advertised to let for business purposes. It had been last used as a sugar-refinery.

The Louvre, the greatest of the modern palaces of Paris, forming a square of 576 feet by 538 feet, was erected on the site of an old castle of the 13th century. The north wing, which was begun in 1541 on the plans of Pierre Lescant, remains a masterpiece of architectural design and monumental sculpture. The principal portion of the great square was completed under Louis XIV. in the latter part of the 17th century, the physician Claude Perrault being the architect. The colonnade of the eastern façade is more admired than any other part of the building.

The Palace of the Tuileries was begun in 1566 by Catherine de Médicis, and enlarged by successive monarchs, while used as a royal residence until it formed a structure nearly a quarter of a mile in length, running at right angles to the Seine. It was connected with the Louvre, which lay to the west, by a great picture-gallery overlooking the Seine, and 1430 feet in length. North of the picture-gallery, and between the two palaces, lay the Place du Carrousel, in the midst of the most magnificent palatial structure in the world. The Tuileries continued to be occupied as the residence of the imperial family; but the Louvre proper formed a series of grand galleries filled with pictures, sculptures, and collections of the most famous, Greek, and Roman antiquities. The Commune attempted to burn the whole pile, but only succeeded in destroying the Tuileries and a corner of the Louvre. The Place du Carrousel enclosed between them and the Louvre is now thrown into the great line of gardens stretching west to the Arc de l'Étoile. In the midst of the old palaces a statue of Gambetta, surrounded by allegorical figures, has been erected. North of the Louvre is the Palais Royal. It forms a mass of buildings, including the old palace of the Orleans family, the Théâtre Français, and a quadrangle of great mansions. The mansions and a large park or garden open to the public, 700 feet long by 300 feet wide. With its avenues and parterres it was long one of the liveliest and most frequented spots in Paris. Its cafés had a world-wide reputation, which has faded, however, since the great improvements of Napoleon III. sent the current of life into other quarters. The most valuable part of the palace, fronting the Rue St Honoré, was set fire to by order of the Commune in 1871. The Palace of the Luxembourg, on the south side of the Seine, was built by Marie de Médicis in the Florentine style, and contains many magnificent rooms, and in 1879 became the meeting-place of the French senate. Close to it a gallery has been constructed for the reception of the works of living artists acquired by the state. On the north bank of the Seine, opposite the island
of the Cité, stands the Hôtel de Ville. It was
burnt by the Commune, but has been rebuilt
and restored in the style of its predecessor, and is now
one of the finest buildings in Paris. On the island
of the Cité stands the Palais de Justice, a vast pile,
also set fire to by the Commune; some parts of it
date from the 14th century, and others are modern.
In the Cour des Consuls are the Courts of
Appeal, and of Police.
Within the precincts of this palace are the Sainte
Chapelle, and the noted old prison of the
Cinquiéme, in which Marie Antoinette, Danton, and
Robespierre were successively confined.
The prison, now reconverted to its medical
use, in which prisoners are lodged pending their trial, constitutes
one of the eight prisons of Paris, of which the principal
is La Force. The Nouveau Bicêtre is designed for
convicts sentenced to penal servitude for life;
St Pélage receives political offenders, St Lazare
is exclusively for women, the Madelonnettes for
juvenile criminals, and Chichy for debtors.

The number of benevolent institutions is enor-
mous. The largest of the numerous hospices or
alms-houses is La Salpêtrière, probably the largest asylums for the insane in the civilized
world, and appropriated solely to old women; Bicêtre receives only men. The Hôpital des
Enfants Trouvés, or Foundling Hospital (q.v.), pro-
vides for the infants brought to it till they reach
the age of maturity, and only demands payment in the
event of a child being reclaimed. The Créche (q.v.)
receives the infants of poor women for the
day at the cost of 20 centimes. Besides institu-
tions for the blind, deaf and dumb, convalescents,
sick children, &c., Paris has many general and
special hospitals, and mental institutions, among
which are the Hôtel Dieu, La Charité, and La
Pitié.
The chief institutions connected with the Uni-
versity of France, and with education generally, are
still situated in the Quartier Latin. The Sorbonne
(q.v.), the seat of the Paris faculties of letters,
science, and Protestant theology, has been rebuilt
and increased in size. The new building was opened
in 1889, when it was announced that a complete re-
organisation of the university system of France was contemplated (see UNI-
VERSITY). The Sorbonne contains lecture-rooms and class-rooms, and an extensive
library open to the public. There gratuitous
lectures are given, and degrees are granted by the
University of France. Near the Sorbonne is the
Collège de France, where gratuitous lectures are
also delivered by eminent scholars and men of
letters, as well as a large number of colleges and
lycees, the great public schools of France for
secondary instruction. Most of them have been
recently rebuilt, filling the Quartier Latin with
huge barricade-like buildings. The Scotch College
stands as it did in the 17th century, five stories
high, with eleven windows in a row, a good speci-
men of the old Paris colleges. At present, owing to
the war between the republic and the Roman
Catholic Church, the schools of the latter are in-
dependent of the university, and there is no faculty
of Roman Catholic theology at the Sorbonne. The
École Polytechnique, the School of Medicine and the
School of Law, the Observatory, and the Jardin des
Plantes, with its great museums of natural history,
partly rebuilt on a grand scale and opened in 1803,
became the property of the city of Paris. The Jardin des
Plantes contains the British Museum, in the number of its books and manuscripts, but its use-
fulness is impaired by the want of a proper esta-
ligne, which makes its treasures less accessible than
they should be.
No city on this side of the Alps is richer than Paris in fine-art collections, and among these the
muséums at the Louvre stand pre-eminent. Among
its chief treasures may be mentioned, in the museum
of antique sculptures, the famous Venus of Milo,
and in the collections of the arts, the great works of the
Italian, Flemish, and Spanish masters. It is im-
possible to do more than refer to the long succes-
sion of galleries in which are exhibited Egyptian,
Assyrian, Elamite, Greek, Roman, medieval, and
Renaissance relics and works of art. The Musée
Carnavalet, the Museum of French politics and
Paris has been specially devoted to the collection
of everything interesting connected with the munici-
pal. On the demolition of the old houses many objects were found which formed the nucleus
of the collection, which is constantly receiving large
additions which make it one of the most interest-
ing of the Paris museums. The Palais des Beaux-
Arts is used as an exhibition of art, manufact-
ures, and architectural models. The Hôtel de
Cluny, connected underground with the Palais
des Thermes, contains the earliest relics of the arts
and usages of the French people, from the ear-
easiest ages of their history to the Renaissance
period. The potteries, sculptures, paintings, arts,
furniture, and tapestries of the middle ages and of
the 16th and 17th centuries are exhibited in the hu-
torical interest and value. The Museum of Artil-
 lery at the Hôtel des Invalides is devoted to arms
and armour, flags and war dresses. The Musée
Guimet, or National Museum of Religions, includes
objects used in religious ceremonies, savage, Indian,
Chinese, &c. The Mint deserves notice for the illus-
sion of its machinery; and the Gobelins (q.v.), or
tapestry manufacture, may be included under the
fine arts, as the productions of its looms are all
manual, and demand great artistic skill. The
Conservatoire des Arts et Métiers, in the Rue St
Martin, contains a great collection of models of
machinery, and class-rooms for the instruction of
workmen in all departments of applied science.
The great Paris exhibitions have all left behind them
important buildings. The Palace of In-
dustry, built in 1854, contains large sections of the
exhibition. The spacious building in which the
exhibition of 1878 took place was named Palace of
the Trocadéro, and is now used for musical enter-
tainments and as an architectural and ethnological
museum. For the exhibition of 1889 was erected
one of the most striking monuments of modern
Paris, the Eiffel (q.v.) Tower.

Paris was surrounded, under Louis-Philippe,
with fortifications costing £2,500,000 sterling, and,
in addition to these, a large number of detached
forts have since been erected. The walls, 37,000
yards in length, are penetrated by sixty-nine open-
ings, fifty-six for gates, nine for railways, two for the
Canals of St Denis and the Ourcq. Through
the two remaining breaks passes the Seine. At
the gates are paid the octroi or town dues, a large
source of revenue to the city of Paris. On the left
bank of the Seine is the École Militaire, founded
in 1752, and used as barracks for infantry and cavalry;
it can accommodate 10,000 men and 800 horses.
Near it is the Hôtel des Invalides, founded in 1670
during the reign of Louis XIV, for disabled
soldiers. The church of the Invalides contains the
sarcothaphus, hewn from a huge block of
Russian granite, in which lie the remains of
Napoleon, deposited there in 1840.

Paris is divided into twenty arrondissements. The
prefect of the Seine is the chief of the
police government, and is appointed by the govern-
ment. There is a large municipal council, chosen
by popular election. Each arrondissement has a
maire and two assistant-councillors. The prefect
of police is at the head of the civic guard or gendarmes, the fire-brigade, and the sargentes de ville or city police, who are armed with three swords. The cleaning, sewerage, and water-supplies of Paris are under the charge of the prefect. Paris is now abundantly supplied with pure and wholesome water; and the sewers have been greatly extended with the street improvements. The same may be said of the lighting, paring of the city, and the street-lighting by gas and electricity. In 1818 public slaughter-houses, or abattoirs, were established at different suburbs, where alone animals are allowed to be slaughtered. Large cattle-markets are kept near the wholesale and markets. There are in the heart of the city numerous halles, or wholesale, and marchés, or retail markets. The principal of these is the Halles Centrales, near the church of St Eustache, covering nearly 20 acres. History.—The earliest notice of Paris occurs in Caesar's Commentaries, in which it is described under the name of Lutetia, as a collection of mud huts, composing the chief settlement of the Parisii, a Gallic tribe, conquered by the Romans. Lutetia soon acquired great strategic importance, due to its lines of defence—the windings and meanders of the Seine and Marne in the north-west, and the forest-clad hills on the north and south. It lay midway between the chief enemies of Rome in Gaul, the Germans on the east and the un subdued Celts of Armorica on the west. In 53 B.C., accordingly, Caesar assembled there the different Gauls, that be the seat of an important Roman town. Two ruins of this period remain south of the Seine. One formed part of the Palais des Thiers, the abode of the Roman governors of Lutetia and afterwards of the Merovingian kings of France. The other ruin is that of the basilica of the Roche-cache, the Roque-cache. The foundations and parts of the old wall were discovered in 1870, and since then excavations have laid them bare. In 1891 they were enclosed in a small park and thrown open to the public. The basilica was 180 feet long by 135 feet wide. It is estimated that it could contain 10,000 spectators of the gladiatorial shows. Lutetia began in the 4th century to be known as Parisus, or Paris. In the 6th century Paris was chosen by Clovis as the seat of government; and after having failed to hold Paris, from 632 to 675, the Odo, who made Aix-la-Chapelle their capital, and in whose time it suffered severely from frequent invasions of the Northmen, it finally became in the 10th century the residence of Hugh Capet, and the capital of the French monarchy. From this period Paris continued rapidly to increase, and in two centuries it had doubled in size and population. The reign of Philippe-Auguste (1180-1223) is the great epoch in the medieval history of Paris. It was then that were erected masterpieces of Gothic art, including the nave, the choir, and the chief façade of Notre Dame and the Sainte-Chapelle. Then was founded the University of Paris, the great theological school of the middle ages, yielding a power over the church second only to that of Rome, and attracting from all parts of western Europe thousands of students, who, on returning to their homes, spread abroad a knowledge of the art and culture of Paris. Philippe-Auguste built a rampart wall encircling towers, one of which, the Tour de Nesle (q.v.), stood on the site of the Palace of the Institute. Outside the wall he erected the castle of the Louvre on the site of the present palace. It became the centre and stronghold of feudalism and the citadel of Paris, which was now, after Constantinople, the greatest city of Europe. In the 18th century the castle was still used as a royal residence, but after the reception of Charles V., there by Francis I. It was pulled down to make way for the new palace. Luckily the walls were not leveled to foundations. A few years ago they were discovered to exist. Galleries have been excavated, and extensive ruins have been laid bare, which now form the most interesting sight of underground Paris. In the middle ages Paris was divided into three distinct parts—the Île de la Cité, on the Île de la Ville, on the right bank; and the Quartier Latin, or University, on the left bank of the river, and on the Montagne St Geneviève. In 1358 broke out the first of the long series of Paris revolutions. It was headed by Etienne Marcel, the famous provost of the Paris merce, who for a time openly ruled the town. Louis XI. did much to enlarge Paris and to effect the disastrous results of its hostile occupation by the English during the wars under Henry V. and Henry VI. of England; but its progress was again checked during the wars of the Huguenots, when the city had to sustain several sieges. On the accession of Henry IV. of Navarre, in 1589, a new era was opened for Paris. The improvements commenced in his reign were continued under the minority of his son, Louis XIII. Louis XIV. converted the old ramparts into thoroughfares, and the old mansions into abattoirs. The regular system of police, established drainage and sewerage works, founded hospitals, almshouses, public schools, scientific societies, and a library, and thus renewed the claim of Paris to be regarded as the focus of European civilization. The Revolutions caused a temporary recession; but the improvement of Paris was recommenced on a new and grander scale under the first Napoleon, when new quays, bridges, markets, streets, squares, and public gardens were created. All the treasures of art and literature, which congregated in his time, were applied to the embellishment of Paris, in the restoration of which he spent more than £4,000,000 sterling in twelve years. His downfall again arrested progress, and in many respects Paris fell behind the middle of the thirteenth century, and, except in one or two streets, there were no side-pavements. It was reserved for Napoleon III. to reconstruct Paris. When he commenced his improvements Paris still consisted, in the main, of a labyrinth of narrow, dark, and ill-ventilated streets. He resolved to pave broad and straight thoroughfares through the midst of these—thus putting an end to the possibility of forming barricades—to preserve and connect all the finest existing squares and boulevards, especially those surrounding the monuments of the home of the family, and, in lieu of the old houses pulled down in the heart of the town, to construct, in a ring outside of it, a new city in the most approved style of modern architecture. With the assistance of Baron Hausmann (q.v.), the Prefect of the Seine, his schemes were carried out with rare energy and good taste. With a fresh supply of water, trees, parterres, and fountains were introduced everywhere, and Paris ceased to produce on visitors the impression that it stands in the midst of a chalky desert. It was converted into one of the greenest and shadeiest of modern cities. Two straight and wide thoroughfares, parallel to and near each other, crossed the whole width of Paris from north to south through the Cité; a still greater thoroughfare was made to run the whole length of the town, north of the Seine, from east to west. The old boulevards were completed so as to form outer and inner circles of spacious streets—the former chiefly
lying along the outskirts of the old city, the latter passing through and connecting in long line of distant suburbs. In the year 1867, when the international exhibition was opened, Paris had become in all respects the most splendid city in Europe. Many further improvements were then contemplated. Financial and political difficulties were, however, the fixed modern P. Declaration spread its new was the, its large appearance reverse to looks the Commune was declared to be a monument of tyranny. The government troops under Marshal MacMahon attacked the insurgents from them and they refused to give up the city. The former succeeded in entering Paris on the 20th of May, and next day the Communists began systematically to set fire with petroleum to a great number of the chief buildings of Paris, public and private. The fire for a time threatened to destroy the whole city. It raged with increasing fury on the 24th, and was not checked until property had been lost to the value of millions sterling, and historical monuments were destroyed which never can be replaced. The horror inspired by the Commune was a time of those wealthy classes from Paris, and it was feared that it would lose its prestige as a European capital. This, however, has not proved to be the case. By the autumn of 1873 all the private houses burned had been rebuilt, the monuments only partially injured had been restored, and the streets and public places were as splendid and gay as in the best days of the empire.

Since the establishment of the republic improvements have been executed little if at all inferior in importance to those of the previous period. New streets have been opened near the Paris Bourse de Commerce and the Post-office; the Champs de Mars, a waste of sand, has been converted into a beautiful garden, in which rises the Eiffel Tower; the museums of the Jardin des Plantes have been rebuilt; the parts of the interior of the Notre-Dame de Paris have been restored, the nave of which, then, was completed. In 1890-91 two great undertakings were mooted—a system of metropolitan railways to connect the great Paris stations with the heart of the city, and the conversion of Paris into a sea-port by the deepening of the Seine, or the construction of a ship-channel to the Channel. The magnificent International Exhibition of 1900 did not attract the vast crowds for whom preparations had been made, and was not financially as successful as was hoped.

Somewhat conflicting opinions are expressed on the part Paris has played in the history of the world. After Athens and Rome, says one writer, it is the city that has made the deepest impression on men's minds. Paris, says another, has carried the torch of civilisation of the 18th century, and done most to spread culture and enlightenment throughout the globe. At this moment, says a third, the inhabitants are the best fed and best clad, the best educated of city populations. These views are generally accepted in France. The Parisians are declared to be a feasible people, dying out, and constantly recruited by immigration from Belgium, Alsace, Switzerland, and Italy. Paris is a modern Babylon; its domestic life, described in French novels, is a mirror of current events of the 19th century. It has been, no doubt, in all these views at different periods of the history of Paris. Certainly it is, however, that in England it is too often forgotten that in Paris drunkenness is almost unknown, that amongst the large section of the population there has always been a pure domestic life, and that the profligacy of the second empire has now ceased to exist.

**Declaration of Paris.**—In 1856 the representatives of the Powers agreed to four points in International Law (q.v.)—viz. (1) Privateering is abolished; (2) the neutral flag covers enemies' goods, excepting Central and South America, from France, Germany, and Spain; gave to England the French colonies in America; and rearranged the possessions of France and England in the West Indies, India, and Africa. The Treaty of 1841, concluded by the Allies soon after the abdication of Napoleon, reduced France substantially to its old limits. That of 1815, after Waterloo, did so more completely, levied a heavy contribution towards the war expenses, and reconstituted the map of Europe on the old lines. The Treaty of 1856 concluded the Crimean War (q.v.). A number of 1878 arranged relations between Britain and Persia.

**Paris.** (1) capital of Bourbon county, Kentucky, on Stoner Creek, 19 miles by rail NE. of Lexington. It contains a military institute, and manufactures whisky, flour, cordage, &c. Pop. (1900) 4603.—(2) Capital of Lamar county, Texas, 98 miles by rail NE. of Dallas. It has manufactories of broom, furniture, saddles, wagons, ploughs, &c. Pop. (1900) 9358.

**Paris.** A genus of plants of the small endemic natural order Triallacia, of which one species, P. quadrifolia, called Herb Paris, is not uncommon in moist, shady woods in some parts of Britain. It
PARIS

PARISH

is rarely more than a foot high, with one whorl of generally four leaves, and a solitary flower on the top of the shoot, followed by a berry. The berry is
reputed narcotic and poisonous, but its juice has
been employed to cure inflammation of the eyes.
The root has been used as an emetic.

Paris, also called Alexander, was, according to
Homer, the second son of Priam and Hebeus,
sovereigns of Troy. His mother dreamed during
her pregnancy that she gave birth to a fire-in
the whole city on fire, a dream interpreted by
Essex or Cassandra to signify that Paris should
originate a war which should end in the destruc-
tion of his native city. To prevent its realisation
Priam caused the infant to be exposed upon Mount
Ida. He was afterwards found by Anchises, who found
him five days after alive and well, a she-bear having
given him suck. Anchises brought him up as his
own son, and he became a shepherd on Mount Ida.
An accident having revealed his parentage, old
Priam became reconciled to his son, who, not infat-
ated by the visit of a river-god, but his mother's
dream was to come true for all that. He was
appealed to, as umpire, in a strife which had arisen
among the three goddesses, Hera (Juno), Athene
(Minerva), and Aphrodite (Venus), as to which of
them was the most beautiful. This question was
soon advantageously flung among them, at a
feast which Joseph had not been invited to, a golden
apple (of discord) inscribed 'To the Most
Beautiful.' Each of the three endeavoured to bribe him. Hera
promised him dominion and wealth; Athene,
military renown and wisdom; Aphrodite, the fairest
of women for his wife—to wit, Helen, the wife of
King Menelaus. Paris decided in favour of Aphro-
dite—hence the animosity which the other two
goddesses displayed against the Trojans in the war
that followed. Paris now carried Helen away from
Lacedaemon, and the modern 'Trojan War,' the
'stape de Helen' is the legendary cause of the Trojan
war (see Helen, Troy). Paris deceitfully slew
Achilles in the temple of Apollo. He was himself
wounded by a poisoned arrow, and went to Mount
Ida to be cured by Euryne; but she avenged her
friend for his unfaithfulness to her by refusing to
assist him, and he returned to Troy to die.

Paris, Comte de. See Bourbon, Orleans.

Paris, Gaston, born 9th August 1839, succeeded
his father, Paulin Paris (1800-81), in 1872 as pro-
fessor of old French at the College de France,
became a member of the Academy of Inscriptions
in 1872, and of the Académie Française in 1896. He
has written a long series of works on old French
literature (La Poétique du Moyen-Âge, 1883-95; La Littérature Française au Moyen-Âge,
2 vol. 1890, &c.), and edited many texts (Le
Romans de Raimond, 1835, &c.).

Paris, Matthew, chronicler, who probably in-
herited his family-name (not mean uncommon
in England), was born about 1290. In January 1217
he entered the Benedictine monastery of St Allans,
grew up under the eye of Roger de Wendover,
and in 1248 was sent by the pope's recommendation
on a mission to repair the financial disorders in the
Benedictine monastery on Monk's Island (Holm)
near Trondhjem in Norway. In July 1251 he
was in attendance at the court at Winchester,
six months later he witnessed the marriage at
York of Henry's daughter to Alexander II. of
Scotland, and in March 1257 he was chosen by
the King during his week's visit to the
monastery. His death occurred about the
middle of 1259. Matthew Paris's principal work
is his Historia Major, or Chronica Majora, a history
from the creation down to the year 1259. The
original edition is that published in 1571 under
the authority of Archbishop Parker; but the
authoritative edition of the work is that edited by
Laurel in the Rolls series (vols. 1872-83). His
conclusion as to its authorship is that down to
the year 1189 it was the work of John de Cella,
abbot of St Albans from 1195 to 1214; that from
that point it was continued by Roger de Wendover
down to the year 1255—the work to this point
being often ascribed to him alone, and known as
the Flores Historiarum; that Matthew of Paris
next transcribed, corrected, and extended (by
interpretation rather than by interpolation) the
work, which, moreover, from 1255 onwards, is
his own. This historian is vigorous, vivid, and
accurate, and his pages are aglow with patriotic
fervour. His Historia Anglorum is abridged from
the greater work by the omission of what relates to
foreign affairs. It was edited by Sir P. Mahlken
in the Rolls series (3 vols. 1866-68). Other works
are the Abbatiae Chronicum (1100-1255); Liber
Additamentorum or Supplementorum; the dubious
Duorum Officiorum Merciorum Regum Vitae,
and the valuable Viginti trium Abbatum S. Albani
Vite. See an article by Dr Jessop in the Quarterly
Review (1890).

Paris Bordone. See Bordonio.

Parish (Lat. parochiae; Gr. paróikìa, 'neigh-
bourhood') is a term used to denote the district
assigned to a bishop or priest. In early times
the bishop arranged all the church work of his
diocese, and the minor churches were served by clergy sent
from the bishop's church. With the establishment of many
endowed and resided parishes were assigned
to resident priests, and titles were, by special gift
or by general rules of law, made payable to
the parson of the parish. In England provisions
regulating to this matter were included among the laws
of Edgar about 970. Parishes were formed on the
basis of previously existing manors and townships:
the lord of the manor often held the Adowson
(q.v.) or patronage of the parish church; and the
holders of their meetings in the vestry of the
church; the parson presided, and he was usually
the principal or the leading one of the Churchwardens
(q.v.). The parish was originally the unit of
administration for poor-law and highway purposes,
but modern legislation has transferred many of
the functions of parish authorities to Boards of
Guardians (see Poor-Laws) Highway Boards (see
Roads), etc. There are about 15,000 civil parishes in
England and 900 in Scotland; they vary very widely in extent and
in population. Thus, Queensferry has an area of
only 11 acres, Kilnallie (pop. 4157) in Lochaber of
444 sq. m. (nearly as large as Bedfordshire); whilst
Wendover in Buckinghamshire (180 sq. m.) has more than
250,000 inhabitants, and Skiddaw (nearly 5 sq. m.) in
Cumberland only 10. The boundaries of an ancient
parish are fixed by custom, the memory whereof
was formerly, and in some cases is still, kept alive by an
annual allotment per head (see Sums, HEATING THE).
Ancient parishes have been divided and altered in many cases
in the exercise of statutory powers; the Local Government Board
possesses large powers of alteration. For ecclesi-
astical purposes populous parishes may be divided
by the exercise of special powers (see Ecclesiastical Commissions); by the exercise of these powers the
number of ecclesiastical parishes has been raised to
about 13,000. The parson or incumbent is a
corporate sole; he has a freehold in his office, and
in the church and churchyard (see Tithes). The
church is only one of the 1571 ecclesiastical
parishes of England; the Churchyard (q.v.) may be used
by Nonconformists. The powers of Churchwardens and Vestry have been greatly limited by the Local Government Act of 1894, which established district councils, and parochial councils, and vestries.

The district councils are mainly the old rural and urban sanitary authorities under a new name, and have charge of highways, &c. The parish meeting in every rural parish includes all persons registered as parochial electors (all registered as parliamen
tary electors are also parochial electors in the counties, even where there is a parish council), the power of adopting the Adoptive Acts (Lighting and Watch- ing Act, Baths and Washhouses Acts, Burial Acts, Public Improvement Acts, Public Libraries Act), and of controlling the expenditure of the parish. When there is no parish council, the parish meet
ning (which must take place at least once a year) appoints the overseers, and may have some of the powers of the parish council conferred on it by the county council. Every rural parish with a popula-
tion of 300 in 1891 (though some parishes are grouped, and some smaller parishes have had a parish
council given them by the county council) has now a parish council of a chairman and from five to fifteen councillors, elected annually at a parish meeting by show of hands, or by ballot, if demanded. The council, which is a corporate body whose expenses are borne by the parish, appoints the overseer, appoints overseers and assistant overseers, has the secular power once exercised by the overseer (rating, nominating constables, &c.), the former powers of the churchwardens, save in church affairs and charities, the powers of the vestry as defined by the Adoptive Acts by the provision of public offices and recre-
ation grounds, the duty of looking after wells, streams, footpaths, rights of way, and minor nuis-
ances, the power of acquiring and holding land for allotments and other local purposes, and the power of adopting various appears of expenditure. Both married and single women are eligible as parish councillors, guardians, rural or urban dis-
trict councillors (not for borough or county coun-
cils). As parochial electors women may attend parish meetings and vote. Husband and wife can-
not be on the same council.

The Vestry of a parish is either a common vestry—a meeting of all the ratepaying inhabitants, presided over by the incumbent—or a select vestry, elected under Hobhouse's Act (1831). In urban parishes it is unaffected by the Local Government Act of 1894; in rural parishes it is no longer ecclesiastical purposes only. The administration of the Poor-laws (q.v.) in England is unaffected by that act, save that now rural district councillors act as guardians. The care of the poor is almost entirely in the hands of the guardians; the over-
seers assist the guardians. The assistant overseers, when not appointed by the guardians, are officers of the parish council. A woman may be an overseer.

See CHURCH-RATES, CHURCHWARDENS, CHURCH-
YARD, POOR-LAWS, VESTRY.

Both English and Welsh parishes are of very ancient date. The Court of Session, acting as the Commission of Teinds, has power to unite and divide parishes, and to erect a disjoined part into a parish *givesal sacra*—i.e. for ecclesiastical purposes only. The poor-law was formerly administered by the Kirk-session in county parishes and by magis-
trates in burghal parishes; but an act of 1845 introduced a system of parochial boards, which since the Local Government Act of 1894 have been superseded by the parish councils. The church fabric is supported by the heritages; there are no churchwardens in Scotland; nor is there any meet-
ing corresponding to the vestry. In the matter of parish schools Scotland was formerly far in advance of England; the policy of the Education Acts is now the same in both countries.

**Parish Clerk.** See CLERK.

PARK, MUNGO, the African traveller, was born 10th September 1771, at Founshielis on the Yarrow, a farmer's youngest child in a family of thirteen. Educated at Selkirk, he was apprenticed to Dr Thomas Anderson, a surgeon there, and afterwards studied medicine in Edinburgh (1789–91). He was then introduced to Sir Joseph Banks by his brother-in-law, James Dickson, botanist, and obtained the situation of assistant-surgeon in the WORCESTER, bound for Bengacoon in Sumatra. On his return in 1793, the African Association of London had re-
ceived intelligence of the death of Major Houghton, who had undertaken a journey to Africa at their expense. Park offered his services as a surgeon, and sailed from England 23d May 1795. He spent some months at the English factory of Pisania on the Gambia in making preparations for his travels, and in learning the Mandingo language. Leaving Pisania on 27th November, and pushing his way to Mando, but when he had nearly reached the place where Houghton lost his life, he fell into the hands of a Moorish king, who imprisoned him, and treated him roughly. Park seized an opportunity of escaping (1st July 1796), and in the third week of his flight reached the Niger, the grand object of his search, at Sego, in 13° 5' N. lat. He followed its course downstream as far as Silla; but meeting with hindrances that compelled him to retrace steps, he pursued his way westward along its banks to Bussa, and from thence, in a few months, to the pod-
ious country till he came to Kanania, in the king-
dom of Mando (14th September), where he was taken ill, and lay for some time. A slave-trader at last conveyed him again to the English factory on the Gambia, where he arrived, 10th June 1797, after an absence of a journey to Africa of seven. Bryan Edwards drew up an account of his journey for the Association, and Park published an account of his travels after his return, under the title of Travels in the Interior of Africa (1799), a work which at once acquired a high popularity. He now married for the second time, his first wife having been a Selkirk friend (2d August 1799), and settled as a surgeon at Pebbles, where, however, he did not feel at home. He told Scott that he would rather brave Africa and its horrors than wear his life out in toilsome rides amongst the hills for the scanty remuneration of a country surgeon; and so, in 1805, he undertook another journey to Africa at the expense of government. As part from Scott on Willianne ridge, his horse stumbled:

"I am afraid, Mungo,' said Scott, 'that is a bad omen.'

"No, Friend Scott," said Park, "that omen is to me a very good one."

*Frets (omens) follow those who look to them.*

When he started from Pisania he had a company of forty-five, of whom thirty-six were Euro-
péan soldiers; but when he reached the Niger in August his attendants were reduced to seven. From Samsarung on the Niger, in the kingdom of Barnbar, he sent back his journals and letters in November 1805 to the Gambia, and embarked in an unwieldy half-ratten canoe with four European companions. Through many perils and difficulties they reached the island, and the canoe was caught in a cleft of rock; they were attacked by the natives, and drowned as they attempted to escape. An account of Park's second journey was published at London in 1815. Mrs Park was in receipt of a government pension till 769
her death in 1840. Two of Park's sons joined the Indian army; Thomas, the second son, perished in trying to penetrate the mystery of his father's death. Park's narratives, which are well written, handle places and names with great accuracy. All classes of travel, and are of inconsiderable value, particularly for the light which they throw upon the social and domestic life of the negroes, and on the botany and meteorology of the regions through which he passed; but he was unfortunately cut off before he had achieved the grand aim of his explorations—the discovery of the course of the Niger (q.v.). Park was tall and robust, and possessed of great hardihood and muscular vigour. "For actual hardships undergone," writes Joseph Thomson, "for dangers faced, and difficulties overcome, together with an exhibit of courage and the virtues which make a man great in the rude battle of life, Mungo Park stands without a rival."

See the Life by Wishaw, prefixed to Journal (1805), and Joseph Thomson's Mungo Park (1890).

Parker, Sir Hyde (1739-1807), a British admiral, of a Devonshire family distinguished both before and after his promotion to his high office in the naval service of the country, served in the American War and in the West Indies, and in 1801 was appointed to the chief command of the fleet which was sent to the Baltic to act against the armed coalition of the three northern states of Russia, Sweden, and Denmark in the Archipel of Copenhagen, in which Nelson engaged contrary to his orders; but by his appearance before Carlskrona he compelled the neutrality of Sweden; and he was on the point of sailing for Cronstadt when the news of the Emperor Paul's death put an end to the hostilities.

Parker, Joseph, a popular preacher and author, the son of a stone-cutter, was born at Hexham, 9th April 1830, and like Spurzheim began to preach in early youth. He studied at Moorfields Tabernacle and University College, London (1852), was ordained pastor of the Congregational Church, Bankury (1855), and became minister of the Cavan- dhill Street Church, Manchester (1859), and of Poultry Chapel, London (1869), now City Temple (opened 1874). He visited the United States in 1888, and received the degree of D.D. from Chicago University. As a preacher he is strong and vigorous, and possesses the quality of rare English; he has not unfrequently posed as an oracle on political and ecclesiastical subjects.

He has published Help to Truth-seekers (1857), controversial discourses with secularists at open-air meetings; Eere Deus (1858; 3rd ed. 1879), being a reply to Eric Hunt; Ad Clerum (1870); City Temple Sermons (1869-70); Inner Life of Christ (1881-82); Apostolic Life (3 vols. 1884); People's Prayer-book (1889); but his most ambitious work is his People's Bible, "discourses upon Holy Scripture, forming a pastoral commentary," of which the first volume, Genesis, appeared in 1883. See Tyne Childe: My Life and Teaching (new ed. 1889).

Parker, Matthew, the second Protestant Archbishop of Canterbury, was born son of a calender at Norwich, August 6, 1534, studied at St Mary's Hostel and Corpus Christi College, Cambridge, took orders, and was elected to a fellowship. He was an ardent student of the Scriptures and of church history, yet, in spite of his strong leaning to the past, from an early period he was interested in the new doctrines. In 1555 he was appointed chaplain to Lord Pole, and soon after he obtained the deanship of the college of St John the Baptist at Stoke near Clare in Suffolk. Here he lived mainly till 1545, his retiring temper finding pleasure enough in his studies and the administration of the college. In 1538 he was created D.D., next a royal chaplain and canon of Ely, and in 1544 master of Corpus Christi Col-
and A Half-Century of Conflict (1892)

Parlement, the name applied in France, down to the Revolution, to certain superior and final courts of judicature, in which also the oEdicts of the king were registered before they became laws.

Of these the chief was that of Paris, but there were fewer than a dozen of them, and they were presided over by the Législateurs of Paris (Toulouse, Grenoble, Bordeaux, Dijon, Pan, Metz, Besançon, Donai, Roven, Aix, Reennes, and Nancy). These, though not actually connected with that of Paris, invariably made common cause with it in its struggles with the royal power. The Parliament of Paris dated from the 14th century, and already consisted of three chambers, the Grand Chamber, the Chambre des Enquêtes, and the Chambre des Requêtes. By 1344 it had grown in numbers and power, and consisted of 3 presidents and 28 counsellors, of whom 44 were ecclesiastics and 34 laeymen. In 1467 Louis XI. made the counsellors irremovable. Its influence grew during the 16th century, and it now began to find courage to deliberate on the royal edicts as well as merely register them, which the king could always force them to do. They were now, for instance, to 'sit by justice' (see BED OF JUSTICE). Neither Richelieu nor Louis XIV. permitted such discussion of their edicts, and both the Regent Orleans and Louis XV. followed their policy. The latter exiled the members from Paris in 1773 for their interference in the struggle between the Huguenots and the Jesuits, and in 1770, on the advice of Manpeon, abolished the old parliament altogether and established the Parlement Maupeson. Louis XVI., however, recalled the former counsellors. These in the last days of their existence were grouped as follows: The Grand Chamber, with 10 presidents and 37 counsellors, of whom 12 were clerics; the three Chambres des Enquêtes, each formed by 2 presidents and 25 counsellors; and the Chambre des Requêtes, in which sat 2 presidents and 12 counsellors.

Parley, Peter. See GOODRICH.

Parliament (Low Lat. parlamentum or parlementum, 'parlamentum, from parla, 'to talk'), a meeting for conference and discussion (see PARLAMENT). In England the name of parliament has been given since the 13th century to the Great Council of the realm—the national assembly which succeeded to the powers exercised by the Witenagrum in the Saxon times. Under the influence of feudal ideas the Great Council became the high court of parliament. As the manor had its courts in which the lord met with his tenants, so the kingdom had its. high court, in which the king met with the different estates or orders of his subjects, and conferred with them as to the enforcement of the good customs of the realm. At first the king claimed to exercise a measure of arbitrary discretion in issuing his writs of summons to parliament; but before the end of the 15th century it was settled and clearly understood that no writ and no summons should always consist of duly qualified representatives of the three estates of the realm—the Clergy, the Lords, and the Commons. The notion that the three estates are King or Queen, Lords, and Commons is a later development.

The Three Estates—The Clergy.—The clergy were represented by the Lords Spiritual, the bishops, who sat among the Lords by virtue of their office. At one time procurors representing the lesser clergy sat among the Commons; but the clergy gave up their right in order to manage their own affairs in Convocations (q.v.). When Convocation gave up its right of taxation clergymen were permitted to vote in the election of members of the House of Commons. It would hardly be correct to say that the
In the House of Commons, and finally rejected. During the reign of George III., peers were created very freely. It was the avowed policy of the younger Pitt to fill the House of Lords with the wealthiest traders and landowners, and so to break down the family and personal factions into which a small aristocratic assembly tends to divide itself.

With this object he conferred peerages so lavishly that the number created by George III. was 388.

In 1799 the Commons formally admitted 'that the judgments of parliament belong to the Lords and not to the Commons.' The House of Lords is the court of appeal for all the United Kingdom; it exercises original jurisdiction in peerage cases, in trials of peers for treason or felony, and on Impeachments (q.v.) by the Commons. When the House is sitting judicially only those members who hold or have held high judicial office take part in the proceedings. Lay peers formerly took part and voted on appeals; but this practice was justly regarded as a scandal.

In 1844 some lay peers announced their intention to vote in the case of the Queen v. Daniel O'Connell, but they were persuaded to retire, and the case was determined by the judges of the House. In its legislative capacity the House may deal with any matter affecting the public interest, and it claims the right to initiate bills which directly affect its own rights and privileges. By a convention of long standing, the Lords respect the Commons in the right to initiate money bills; they may accept or reject a money bill, but they do not amend it in detail. Any member of the House may introduce a bill, and ask that it may be read a first time; the 'reading' is of a formal character—the bill is laid on the table, and the title is read over by a officer. If the House entitles the clerk to read the bill a second time it accepts the general principle of the measure; the bill is then referred to a committee of the whole House, or to a select committee, to be amended in detail; it may then be reported to the House and read a third time and passed. If the bill is afterwards passed, or has already been passed by the Commons, it only requires the royal assent to become an act of parliament. This assent is given by the sovereign in person, or by commissioners representing the sovereign; the Lords are represented by the chancellor of the exchequer, who, with the Speaker, attend at the bar of the Lords; the clerk of parliaments utters the Norman-French formula, 'Le Roy (or La Reine) Ie veult.' In the case of a money bill the royal assent is coupled with an expression of thanks for the 'beneficence' of parliament. The clerk endorses on the bill the date of the royal assent which turns it into an act.

If the sovereign were to refuse assent the form would be 'Le Roy (or La Reine) s'avisera'—the King (or Queen) will think about it. But since the cabinet council becomes the chief power in the state this form of refusal has never been heard.

Ministers take the lead in the business of legislation; they obtain the assent of the sovereign on the one hand, and of parliament on the other; all open conflict of powers is avoided. Queen Anne refused assent to the Bill for the Surplus Land (1740) for the first time the royal assent has been given to every bill which passed the two Houses. Bills which await the royal assent are usually deposited in the House of Lords for that purpose; but a money bill, after passing the Lords, is returned to the Speaker of the Commons, and a message sent to the bar of the Lords to receive the royal assent.

Precedence and Privileges.—Members of the House of Lords were formerly required to sit according to their precedence, but this rule is no longer observed. The bishops sit to the right of the woolsack; on the same side is the bench usually
be ordered two knights to be sent to parliament from each shire. Thirdly, there were burgesses and citizens, representing the self-governing towns of the kingdom. The burgesses also found it hard to bear the expense of attending parliament; they usually received allowances and some legal authorities have held that a member may still recover his 'wages' if he chooses to sue for them. No member of parliament now receives any pecuniary allowance. Payment of members is often advantaged the government, and the cultivated population ought to be represented by men of their own class; it is resisted on the ground that paid members would be officials or delegates, not free representatives of the general body of citizens.

Happily for the cause of popular government, the knights and burgesses were soon welded together in one body; there has never been any legal difference between county members and borough members. Early in the history of parliament (the date cannot be exactly determined) the Commons retired to consider their own affairs in a separate chamber, and one of the papers was printed by order. The House of Lords declares its own privileges; but in doing so it is bound by the law; it cannot create a new privilege by mere declaration. Persons guilty of breach of privilege are censured, fined, or imprisoned for a time certain or during pleasure. The privilege of the House may be used to protect the House and its committees, and all persons having lawful business before them, together with their counsel, solicitors, and agents.

Officers.—The chief officer of the House of Lords is the Chancellor, or Keeper of the Great Seal, who acts as speaker for formal purposes; he does not keep order; the Lords keep their own order. It is not even necessary that he should be a lord of parliament, and he sits on the woolpack, which is supposed to be outside the House. Deputy-speakers are appointed when necessary; and there is a salaried Committee of Members who exercises considerable powers, especially in regard to private bills. The Clerk of the Parliaments is appointed by the crown; and the Gentleman Usher of the Black Rod is one of the queen's ushers, whom she permits to act as the messenger and executive officer of the Lords. The judges and law-officers rank as assistants of the House; they are summoned to attend in a court of justice, and their personal name is mentioned in the House; the judges also come in and sit together on the woolpack when the Lords desire to take their opinions on a point of law. Formal messages to the Commons are conveyed by the Usher of the Black Rod. Judges and Masters in Chancery were formerly employed for the same purpose, but the Commons came to treat these ceremonies with levity, and messages now pass from one House to another by the hands of their respective clerks, except on certain urgent occasions, such as the opening of parliament. Formerly there was a question whether the Lords, when the two Houses differed, a formal conference was held in the Painted Chamber, the Lords sitting with their hats on, the Commons standing and uncovered; but the modern practice of party government renders these conferences unnecessary.

The Clerks. The clerk of the House of Commons, the 'clerk regni,' included originally three classes of persons. First, the proctors of the lesser clergy, who disappeared at an early date. Secondly, the knights of the shire, who were chosen by the lesser barons and the great officers of state. Thirdly, those lords held their land by honourable tenures, but they could not bear the expense of attendance in parliament. As early as the time of King John they were represented by delegates; and Simon de Montfort gave effect to the same principle when
with cases of privilege, and with questions relating to the election and conduct of their members. Election petitions used to be tried by committees of the House, but this practice led to great abuses, and in 1808 these petitions were remitted to the judges for trial. The House may exclude, suspend, or expel a member for misbehaviour; but it was settled in the case of John Wilkes (q.v.) that expulsion creates no disqualification; the person expelled may be re-elected. Burke and other high authorities attach great importance to this rule of the constitution. If the House could disqualify a member, the majority might attempt to strengthen itself by expelling the leaders of the minority. In 1711 Sir Robert (then Mr) Walpole was expelled the House, and there is reason to believe that the vote in his case was decided by considerations of party, and not by his guilt or innocence of the charges made against him.

As representing the whole community, and not merely a limited order, the Commons have long been accustomed to take the lead in the financial and legislative business of parliament. Since the Great Charter (1215) they have had the power of laying taxes, although that power is not to be levied without consent of parliament; and in the reign of Richard II., if not earlier, the Commons laid claim to the 'power of the purse.' It is now established beyond doubt that the Commons have an exclusive right to vote supply, and a preponderance in the means by which money may be raised. This right is respected by the Lords; the last conflict between the Houses occurred in connection with the repeal of the paper duty in 1809. Estimates of public expenditure are laid before the Commons by ministers, and a general declaration of supply is taken. This is a committee of the whole House; the Speaker leaves the chair when the committee begins; the Mace (q.v.) is taken from the table; the Chairman of Committees takes his seat at the table; and the discussion which follows is of an informal character, members being allowed to speak more than once to the same question. When some of the necessary votes have been taken in supply the House resolves itself, in like manner, into a committee of ways and means. The resolutions adopted in committee are embodied in bills, which are sent up for the assent of the Lords. At the close of the financial year (i.e. about the end of March) the Chancellor of the Exchequer, in committee of the whole House, opens his Budget (q.v.) of expenditure and revenue for the coming year. Legislative business is conducted with the same forms as in the Lords; but a member must ask leave of the House to introduce a bill. If a bill is read a second time it is considered in detail by a committee of the whole House, or by a select committee. A committee always reports its proceedings to the House, the Speaker resuming the chair for that purpose. Besides performing these financial and legislative duties, the House of Commons acts as a 'grand inquest' to inquire into all matters of public concern. It is specially bound to watch the conduct of ministers, and to inform the sovereign whether it possesses the confidence of the nation or not. In other words, the support of the Commons is necessary to the existence of a ministry, while a ministry may hold power though its supporters are in a minority in the Lords. Ministers take the lead in all important business; and party dissensions tend to reduce, if not to destroy, the influence of private member to comparative insignificance.

Union with Scotland and Ireland—Parliamentary Reform—Democracy.—The functions of parliament have been rendered more important and difficult by the political changes of the last 200 years. In the first place there is now only one legislature for the United Kingdom. Down to 1707 Scotland had an independent parliament; the three estates of that kingdom sat together in one house, and the conduct of business was for the most part left to a smaller body called Lords of the Articles. At the Union the Scottish parliament ceased to exist; it was agreed that 170 members from Scottish rural districts (i.e. the assembly of peers at Holyrood, at the opening of a new parliament) should sit in the House of Lords, and not less than forty-five Scottish members in the House of Commons. The Irish parliament was an assembly of a more or less provincial character, involving no executive function. Its existence was conceded, under pressure, in 1782, but it never obtained effective control over the executive (see GRATTAN). By the Act of Union the Irish parliament was taken away; it was agreed that twenty-eight Irish peers (elected for life) should sit in the House of Lords, and 100 Irish members in the House of Commons. Thus the English parliament became the parliament of the United Kingdom. By the acts extending toleration to Roman Catholics (1829), Jews (1858), and Secularists—under the Oath (q.v.) Act of 1834—the laws excluding Catholics from military, civil, and parliamentary life, and new questions have arisen for legislative treatment. Successive Reform acts have widened the democratic basis of the House of Commons; the Act of 1832 gave power to the heads of the minority to introduce, in a majority of the House of Lords, new and old boroughs, and to reduce the number of Catholic peers. The Act of 1867 and 1884, by admitting all householders of £10 to the franchise, have given a preponderance of voting power to the working-classes. One result of these successive changes is that the Commons are now 670 in number; they are, in fact, much too numerous for a deliberative assembly. The collective influence has been diminished, perhaps even eliminated, in either House; but questions of imperial policy occupy a small share of the time of parliament. With the advance of democracy, the sphere of legislation has been extended; large schemes for promoting education and sanitary reform, for regulating mines, factories, and shipping, and for the creation of new executive departments and local authorities are brought forward by all political parties. Each party makes its power felt by pushing its own measures and by dilatory resistance to the measures of its opponents. Constructive legislation has been reduced to an art; the labours of those who lead the House of Commons have become intolerably heavy, and the old rules of debate are found unequal to the strain of political conflict. In 1882 the House adopted new rules of procedure, and these rules were further amended in 1887. A motion for the closure of a debate may now be put at any moment, with the assent of the Speaker or Chairman. But a question for the closure of debate is not decided in the affirmative unless it appears that the motion is supported by more than 200 members, or is opposed by less than 40 and supported by more than 100 members. Dilatory motions for adjournment have been checked; tedious and irrelevant speakers may now be stopped by the chair; a member 'named' to the House as disregarding the authority of the chair may be expelled on the decision of the House.

House of Commons Officers.—The chief officer of the House of Commons is the Speaker, who is chosen by the members from among their own number, at the opening of a new parliament. The Speaker-elect presents himself at the bar of the Lords for the approval of the Crown. He is a member of the House of Commons and presides at its meetings, in a dignified and formal form of words by the Lord Chancellor. The Speaker then lays claim to the ancient privileges of the Commons; on returning to his own House he takes the oath before the other members. Inducted with these forms, the Speaker becomes the president and spokesman of the House, with authority
to keep order. He refers all questions of importance to the House; but his own position is one of great influence and dignity; he is the First Commoner in the kingdom, and takes precedence as such. The Chairman of Committees presides in committee of the whole House; he is also employed for general service as Deputy-speaker. The Assistant Clerk of Parliament acts as clerk of the House: There are two other clerks; their chief duty is to keep the Journals, which are accepted by all other authorities as evidence of what is done by the House. The Sergeant-at-arms is the executive officer of the House.

Summoning Parliament.—When the sovereign is advised to summon a new parliament notice of that intention is given by proclamation. A writ of summons is sent to each lord of parliament; the Scottish peers elect the representative peers. A writ is also sent to the returning-officer of each constituency, commanding him to hold an election, and to return the name of the person elected. In counties the sheriff acts as returning-officer; in Scotland he acts also for burghs within his jurisdiction; in English boroughs this duty is commonly performed by the Lord Provost. In charge of the returning-officer is borne by the candidates, an arrangement which is regarded with disfavour by those who wish to make it easy for poor men to enter parliament.

The Places represented in the House of Commons are counties and county divisions, boroughs and wards of boroughs, and universities. By the plan of redistribution adopted in 1834—83 the more populous counties and boroughs are divided into districts, each of which elects a single member. It is both convenient and fairly convenient, and will probably hold its own in spite of the advocates of proportional representation. The seats allotted to the universities have been the cause of some controversy. In old times a university was a kind of borough within a borough; Oxford and Cambridge obtained at an early date the privilege of sending burgesses to parliament; Trinity College, Dublin, enjoyed a similar privilege, and now sends two members to Westminster; London University now elects one member, and the fourteen other universities elect two members in all those cases the graduate members of the university. Of course university men, if qualified, vote also for the places where they reside or have property, and this double representation is objected to as being inconsistent with the right of voting to themselves. There is also a considerable body of opinion hostile to all double qualifications; ‘one man one vote’ has been for some time a popular cry.

Electors.—The voters entitled to take part in the election are those whose names are on the register. Registration was introduced after the Reform Act of 1832; and the present law affords much more satisfactory means of proving and testing claims to vote than the rough and ready methods formerly in use. Lists of voters are made out by local authorities, and carefully revised, in England by returning-officers appointed for the purposes, in Scotland by the sheriff or his substitute in a registration court. The persons entitled to be placed on the register are male persons over twenty-one, not being peers, not disqualified by alienage, office, or employment, unemployed university students, or those who have corrupt practices, or receipt of parochial relief, and possessing any of the property qualifications required by law. Before 1832 county members were elected in England by the freeholders assembled in the county court; an act of Parliament has substituted for that method of election, and these tenements were of the yearly value of forty shillings; in some boroughs the right of election belonged to a limited number of persons having freeholds or leasehold tenements within the boroughs; in others the inhabitants paying scot and lot voted; in others, again, the right was restricted to members or officers of the corporation. In Scotland the county qualification was a forty-shilling land of old extent, or land not of old extent rated in valuation books at £400; in Edinburgh the election was by the town-council; the member for each group of royal burghs was chosen by delegates appointed by the town-councils. In Galt’s novel, The Provost, there is a graphic and truthful description of a burgh election under the old system, and the idea that land and offices were modelled on the English system; on the passing of the Roman Catholic Emancipation Act in 1829 it was thought prudent to disfranchise freeholders under £10 a year. These old franchises have been in part destroyed and in part preserved by successive acts of reform. The statute law on the subject is voluminous and complicated, and the work of simplification is beset with difficulties; the opposition is always ready to suspect the party in power of what the Americans call ‘gerrymandering’—i.e. of readjusting the electorate to suit its own interests. See Corporations.

The qualifications which now entitle a person to be registered and to vote are classified by Sir W. Anson as follows: (1) Property.—In England freehold of inheritance of forty shillings yearly value, or freehold for term of thirty years or more, leasehold of £5 yearly value, leasehold of £5 yearly value for a term of sixty years or more, leasehold of £50 yearly value, if held for a term of twenty years or more, will qualify a person to vote in counties, and in towns which rank as counties. In Scotland land or heritage of £5 yearly value, leasehold of £10 yearly value held for life or for fifty-seven years or more, leasehold of £50 yearly value held for nineteen years or more will qualify for the county franchise. In Ireland freehold of £5 net annual value, rent charge or leasehold for life of £5 annual value, leasehold of £10 value held for sixty years or more, leasehold of £20 value held for fourteen years or more will qualify for the county franchise. Special rules have been made to prevent the multiplication of small freehold franchises for the purpose of ‘faggot-votes,’ &c. (2) Occupation. The occupier of land or tenements of the yearly value of £10 is qualified to vote in any part of the United Kingdom, but the mode of ascertaining the value varies. In English and Scotch boroughs residence in or within miles of the borough is required; and in all parts of the United Kingdom this franchise is made to depend on payment of rates. (3) Residence. The inhabitant occupier of a dwelling-house, or of any part of a house occupied as a separate dwelling, is qualified; throughout the United Kingdom this franchise is made dependent on payment of rates. Lodgers occupying rooms of the yearly value (unfurnished) of £10 are also qualified. Certain rights of resident burgesses and freemen in English boroughs were preserved by the Act of 1832, and the livemembers of the City Companies retain the right to vote in the City of London.

Candidates.—Conduct of the Election—Election Petitions.—On receiving the writ for an election the returning-officer fixes a day on which the names of candidates, or at least the names of such candidates as they may desire, may be received. Any candidate is free to withdraw from the contest, by giving notice that he will not stand. Any petition in respect of the election which is delivered to the returning-officer or to the city clerk is required to be presented in the court of sessions, and evidence adduced. Any candidate is required to have an agent for election expenses, and in promoting his candidate he is bound to receive and give evidence of all expenses, and that the total expenses are kept within the limits prescribed by the Corrupt Practices Act, 1883 (see Bribery). If more candidates come forward than
there are seats to be filled, a day is fixed for taking a poll of the electors; rooms or booths are fitted up for that purpose; each polling-place is supplied with a ballot-box, voting-papers, &c., and presided over by the returning-officer or one of his deputies. The returning-officer in each county is the person opposite the name of the candidate of his choice; his paper is folded up by himself and dropped into the box; elaborate rules are made by the Ballot Act, 1872, to protect the secrecy of the vote (see BALLOT). Any material infraction of the law in conducting an election may be made the ground of a petition; the petitioners are required to find security for the costs; the petition is tried by two judges, who decide such questions of law and fact as may be raised, determine whether the person petitioned against has been duly elected or not, and report to the Speaker the result of their inquiry. If there is reason to believe that corrupt practices have extensively prevailed, commissioners may be appointed to make inquiry and report, and persons guilty of criminal offences may be prosecuted. The foregoing rules apply to the House of Commons. In the conduct of an election to fill a vacancy in the House of Commons caused by death, expulsion, or acceptance of office under the crown, the law does not permit a member of parliament to resign; if a member wishes to retire he applies to the Secretaries of the Treasury for the writ of election for the Old Hundreds (q.v.), and the acceptance of this has the effect of vacating his seat. When a member accepts high political office, as a general rule he vacates his seat, and must present himself for re-election.

Meeting of Parliament—Acts of Parliament.—When the Lords and Commons assemble at Westminster the Commons are directed to choose a Speaker. This having been done, and the members of both Houses having taken the oath of allegiance, the causes for which parliament has been called together are read to the Speaker in the King's or Queen's Speech, which is read by the sovereign in person, or by the Lord Chancellor in the sovereign's presence, or by one of the lords commissioners who represent the sovereign in absence. The two Houses are free to take up matters not laid before them by the crown; business is now begun in each House by reading a bill pro forma, in order to assert the right of free deliberation. Two members are chosen in each House by ministers to move and second an address in answer to the royal speech; in the Commons this motion is a call to the House. The debate on which the whole policy of the government is attacked by the opposition. Such are the forms in which the first session of a new parliament is begun. Each House may adjourn at its own discretion from day to day and for the customary holidays. The session comes to an end when parliament is prorogued by the crown; prorogation puts an end to all sessionsal orders and to all pending business, except impeachments, writs of error, and appeals to the House of Lords. The public acts of parliament are passed in a session form one statute, which is divided into chapters for convenience of reference. Thus, the 30 and 31 Vict. chap. 20' means the 20th chapter of the statute law made in a session which began in the 30th and continued into the 31st year of Queen Victoria's reign—in other cases copies of bills and statutes are engrossed for preservation among the rolls of parliament, and printed copies are sent to judges and magistrates; but no form of publication is required to give validity to a statute; all subjects are bound to take note of and obey the law. In the course of a statute the courts are guided by the intention expressed in the act itself; they will not look at the arguments or assurances addressed to parliament in the course of debate. An act comes into force as soon as it receives the royal assent, unless some other time has been indicated in the act. It is a rule that no bill may be introduced without previous notice in the sitting; at times it has been necessary to prorogue parliament in order that a rejected bill may be brought in again without delay.

Divisions—Committees.—A division is taken in either House by the voices of those present, the lords and commons voting by 'Aye' and 'No.' No question is put, and the Commons 'Aye' or 'No.' If the Speaker's decision as to the result of the vote is challenged, members pass out into the lobbies, and are 'told' or counted by members appointed for that purpose. In case the numbers are equal, in the Lords the question is decided in the negative; in the Commons the Speaker gives a casting vote. Matters which cannot conveniently be dealt with in the House are referred to a committee of the whole House, such as has already been described, or to a select committee. Witnesses may now be examined and cross-examined by them.

When a private bill is sent to a committee, the promoters and opponents attend with their counsel and agents; the inquiry partakes of a judicial character. The expense of proceedings before parliamentary committees is very great, and many proposals have been made over the system: a bill was before parliament in 1891 by which it was proposed to create a local tribunal to deal with Scotch private bills. In the House of Commons there were formerly four grand committees, for religion, for grievances, for courts of justice, and for trade. These were discontinued in 1832; in 1882 two standing committees were appointed for the consideration of bills relating to law and courts of justice and to trade. These standing committees have done less to lighten the labours of the House than was at first expected; it is found that time may be wasted by reopening in the House questions which have been already discussed at length in the committee.

Prorogation and Dissolution.—When parliament has been prorogued it may be summoned to meet for another session; the new session is opened with the royal speech from the throne, which is now begun in each House by reading a bill pro forma, in order to assert the right of free deliberation. Two members are chosen in each House by ministers to move and second an address in answer to the royal speech; in the Commons this motion gives rise to a whole debate on which the whole policy of the government is attacked by the opposition. Such are the forms in which the first session of a new parliament is begun. Each House may adjourn at its own discretion from day to day and for the customary holidays. The session comes to an end when parliament is prorogued by the crown; prorogation puts an end to all sessionsal orders and to all pending business, except impeachments, writs of error, and appeals to the House of Lords. The public acts of parliament are passed in a session form one statute, which is divided into chapters for convenience of reference. Thus, the 30 and 31 Vict. chap. 20' means the 20th chapter of the statute law made in a session which began in the 30th and continued into the 31st year of Queen Victoria's reign—in other cases copies of bills and statutes are engrossed for preservation among the rolls of parliament, and printed copies are sent to judges and magistrates; but no form of publication is required to give validity to a statute; all subjects are bound to take note of and obey the law. In the course of a statute the courts are guided by the intention expressed in the act itself; they will not look at the arguments or assurances addressed to parliament in the course of debate. An act comes into force as soon as it receives the royal assent, unless some other time has been indicated in the act. It is a rule that no bill may be introduced without previous notice in the sitting; at times it has been necessary to prorogue parliament in order that a rejected bill may be brought in again without delay.
electors than they would be if they were constantly led above, lid to rise in election.

'Omnipotence' of Parliament.—In foreign countries the jurisdiction of the law is limited, and the executive officer has the right to enforce a law by a writ; but in the United States the legislature and the executive have unlimited power, either in the way of constituting the law or in enforcing it. The case is similar also in the United States, and the Constitution is as potent as the Constitution of the United States.

The other legislature of the empire is the Lords, the Upper House of which is the Commonwealth and the Lower House of which is the Commons. They are both elected for a term of years, and the Sessions of the Lords and the Commons are held in the same place and at the same time.

Parliamentary Returns.—Each House may obtain information from the executive departments by asking for returns and papers. In dealing with such a department, the power of parliament is, in the words of Sir Edmund Coke, 'as great as the power of God, being the highest power that can exist in the realm of kings or emperors.'

The other legislative authorities of the empire act within the limits laid down for them by parliament. If a colonial government, for instance, wishes to deal with some matters in the colony, it must seek the power of parliament within legal limits, it is not easy to decide.

Petitions to Parliament.—Petitions may be addressed to either House of Parliament by British subjects and persons resident in the British dominions; a petition must be presented by a member of the House to which it is addressed, except petitions from the corporation of London, which are presented by the sheriffs of London at the bar. The Lord Mayor of Dublin has also been advised to present a petition, and the same privilege would probably be conceded to the Lord Provost of Edinburgh. It was formerly not unusual for the member presenting a petition to make a speech, but the standing orders of the Commons now forbid this to be done. There is a committee of public petitions which reports twice a week during the session.

Constituencies.—The following table shows the number of members sent to the House of Commons by constituencies of the United Kingdom; the names of the electoral divisions of a county or borough not being generally specified when they are all simply taken from the points of the compass, north, north-east, central, &c.

For the history of parliament, see the constitutional histories of Stubbs, Hallam, and May; for its laws and customs, May's Parliamentary Practice, Anson's Law and Custom of the Commons, and Lloyd's History of Parliament. For its relations with the executive, we especially Todd's Parliamentary Government in England. The details of electoral law will be found in the works of Rogers (Englund), Badenoch Nicol- son (Scotland), and W. H. Mann (Ireland). See further G. H. Smith's History of the English Parliament (2 vols., 1892); G. L. Thomson's The Development of Parliament in the Nineteenth Century (1895); also Dow's Parliamentary Companion, Bartholomew's Election Hand- book since 1837 (1880), and Adam's Political State of Scotland in
Parma, a town of Italy, formerly the capital of the duchy of Parma, is situated on the ancient Via Emilia, 123 miles S. from Rome, and 275 from Bologna, and 79 SE. of Milan. The town is surrounded by walls and has a citadel (1591); the streets are straight and wide. Of the sixty or more churches the chief is the cathedral (1059-74), built mostly in the Lombardo-Romanesque style, with frescoes by Correggio. Other notable edifices are the baptistery, one of the most splendid in Italy, begun in 1196 and completed in 1281; the church of Madonna della Steccata (1521-39), containing Moses breaking the Tables of the Law and other paintings by Parmigianino, and the tombs of the Farnese dukes, the church of St John the Evangelist (1510), with frescoes by Correggio; the ducal palace, containing art-galleries (Correggio's works), a library (214,000 vols. and 4,500 MSS., including many incunabula and parchments, &c.); and numerous other palaces, public and private. There are also a university (1599), with nearly fifty teachers and more than two hundred students, a music school, a museum of antiquities, &c. The principal industrial products are pianofortes, silks, cast-iron wares, woolens, earthenware, soap, &c. There are cattle, corn, and silk markets. Pop. (1897) 52,700. Founded by the Etruscans, Parma became a Roman colony in 183 B.C. After the fall of the western empire it was known as Chrysolopolis, the modern Parma, a stony and barren waste. The latter part of the 17th century was a period of great political and religious strife; and in 1655 the city was taken by the French, who passed over it into the hands of the pope in 1611. Pope Paul III. of the house of Farnese (q.v.) incorporated them (1545) as a duchy for his natural son Pier-Luigi, the grandfather of the celebrated Alessandro Farnese, regent of the Low Countries. On the extinction of the male line of Farnese in 1731 the duchy passed to Don Carlos of Spain, but was transferred to Austria four years later. In 1748 it was restored, along with Genoa, to the Spanish Bourbons. In 1796 it was seized by France. In 1802 it was incorporated with France, and in 1814 it was granted to the Spanish Bourbon Maria Louisa. On her death in 1847 it passed to the Bourbon Duke of Lucca. From this time until the incorporation with the kingdom of Italy in 1860 the duchy was in a most unsettléd condition: the people were strongly revolutionizing in feeling; and desired a union with Sardinia; but the rulers were reactionary and, supported by Austria, successfully beat down all attempts at revolution until after the battle of Magenta, when the Austrian troops withdrew and the duchy fell.

Parmenides, a Greek philosopher of Elea (Velia), in Lucania, and in the opinion of the ancients the greatest member of the Eleatic School (q.v.), flourished about the middle of the 5th century B.C. Nothing is known with certainty regarding his life, but Plato tells us he visited Athens in his old age together with his pupil Zeno, and conversed with Socrates, then quite a youth—an anachronism most probably introduced to account for the influence which the philosophy of Parmenides undoubtedly exercised on that of Socrates and Plato themselves. Parmenides, like his master Xenophanes of Colophon, sometimes regarded as the first of the Eleatics, surrounded his philosophy in verse—his only work being a didactic poem named the Neir. The extant remains have been rendered into English hexameters by Thomas Davidson (Journal of Speculative Philosophy, St Louis, 1870), and paraphrased in English prose by W. L. Courtney (Studies and Philosophy, 1882). The leading design of this poem is to demonstrate the reality of Absolute Being, the non-existence of which Parmenides declares to be inconceivable, but the nature of which, on the other hand, he admits to be equally inconceivable, inasmuch as it is dissociated from every limitation under which man thinks. The permanent unity of the universe is thus the ultimate object of knowledge. Parmenides is not a theologian in speculation, seeking rather to identify his Absolute Being with Thought than with a personal God.

The best edition of his fragments is in S. Karstan's Philosophorum Graecorum Reliquiae (Amst., 1833). See also the histories of philosophy of Brandis, Erdmann, Schweger, Ueberweg, and Zeller.

Parmigianino, or Parmigianino, the nickname of Girolamo Francesco Maria Mazzola, painter of the Lombard school, and the most distinguished of those who followed the style of Correggio, was born at Parma, 11th January 1504. He began to paint when little more than fourteen years of age. In 1525 he went to Rome, and was favourably noticed and encouraged by Clement VII. When that city was stormed by the imperialists under Constable Bourbon in 1527 Parmigianino sat calmy at work on his picture of 'The Vision of St Jerome' (now in the National Gallery, London), and was protected from the soldiers who burst in upon him by their leader. After this event he left Rome for Bologna, where he painted various works, including a celebrated altarpiece, the 'Madonna and Child,' and returned to Parma in 1531. Having engaged to execute a series of frescoes in the church of St Mary of Steccata, and having got pay- ment in advance, he delayed to a fault, and when his work that he was thrown into prison for breach of contract, and on being released fled to Casal Maggiore, in the territory of Cremona, where he died on 24th August 1540. His best-known picture is 'Cupid Bound,' which he painted portraits too, as of 'slapping a Bow,' he painted portraits too, as of Charles V., Amerigo Vespucci, and himself.

Parnahyba, a river of Brazil, rises in the Serra Mangabeiras, about 9° S. lat., and thorough- out its course (650 miles) forms the boundary between the states of Maranhão and Piauí. It enters the Atlantic by six mouths. The stream is swift, but navigable by bateaux for nearly 550 miles. On the east bank, 14 miles from its mouth, is the unhealthy town of Parnahyba, with a considerable trade. Pop. 8000. See also PARANÁ.

Parnassus, a mountain in Phocis, regarded by the ancient Greeks as the central point of the earth. On its southern slope lay Delphi (q.v.), the seat of the famous oracle of Pythias; the oracle of Castalia (q.v.). The highest peak (9036 feet) was the scene of the orgies of the worship of Dionysus (Bacchus); all the rest of the mountain was sacred to Apollo and the Muses, whence poets were said to 'climb Parnassus;' a phrase still thus employed.

Parnell, CHARLES STEWART, Irish politician, was born at Avondale, in County Wicklow, June
28. 1846. His father belonged to an old Cheshire family, which purchased an estate in Ireland under Charles M. Parnell the poet and Sir Henry Brooke Parnell, created Baron Congleton in 1841. His great-grandfather was that Sir John Parnell who was long Chancellor of the Irish Exchequer, and an active supporter of Grattan in his struggle against the Union; his father, Sir James, was the first manager for Captain Thomas Wicklow, and published in 1819 a foolish political novel, anything but Irish in sentiment: his mother, Delia Tudor Stewart, was daughter of Admiral Charles Stewart of the United States navy. He was educated at Yeadon and elsewhere in England under private masters, and was for some time a member of Magdalene College, Cambridge, but took no degree. In 1874 he became High Sheriff of County Wicklow; next year he contested County Dublin without success, but in April 1875 was returned as an avowed Home Ruler for County Mayo. He attached himself to Joseph Biggenden, member for Carn, who was the first to discover the value of deliberate obstruction in parliamentary tactics, and during 1877 and 1878 he gained great popularity in Ireland by his audacity in the use of the new engine. There were great scenes of violence and excitement, and the new horror of all-night sittings became familiar to the House of Commons. Throughout the struggle Parnell showed equal audacity and coolness, and acquired a mastery of parliamentary forms. Mr. Butt, the Irish leader, discovered of this incautiousness of Parnell and of a obstructive policy, but his influence quickly gave way before Parnell's, and in May 1878 he died. The year before Parnell had been elected president of the English Home Rule Association. He now threw himself with energy into agrarian agitation, gave it his whole soul—'Keep a firm grip of your homesteads'—at Westport in June, and in October was elected president of the Irish National Land League, which had been founded by Michael Davitt. Mr. Parnell next visited the United States to raise funds for the cause, was allowed like Lafayette and Bigot to address congress itself, and carried home £70,000. At the general election of 1880 he was returned for the counties of Meath and Mayo and for the city of Cork, and chose to sit for the last. He was now formally elected chairman of the Irish parliamentary party; twenty-three votes over eighteen for Mr. Sunley. Meanwhile the agrarian agitation grew, and in a speech at Ennis, September 19, 1880, he formulated the method of boycotting as an engine for punishing an unpopular individual. Mr. Gladstone's government now came to the conclusion that the objects of the Land League were contrary to the law, and in December put Parnell and several other members of the executive on trial, but the jury finally failed to agree. Next session the government brought in a Coercion Bill, which Mr. Parnell opposed vigorously, and afterwards was ejected from the House, after a stormy scene, together with thirty-four of his followers, February 3, 1881. Mr. Gladstone next carried his famous Land Bill, but this Parnell refused to accept as a fraud for the results of certain test cases before the new Land Court were not satisfactory. On the 17th October Mr. Gladstone sent him to Kilmainham gaol, and there he lay till released on May 2, 1882, after some private negotiations with the government conducted through the medium of Captain O'Shea. Mr. Forster resigned the Irish secretaryship in consequence of the release, and next followed the terrible tragedy of Phoenix Park, of which Parnell in his place in the House of Commons expressed his detestation. The Crimes Act was now hurried through parliament in spite of the strenuous opposition of the Irish party. Already the Land League had been proclaimed as an illegal association after the issues of the Bill, but in the autumn of 1884 the nationalists succeeded in reviving it under the name of the National League, and Mr. Parnell was elected its president. The year before the sum of £35,000, mostly raised in America, had been presented to him by his admirers. After an unsuccessful parliamentary campaign for Carlow in 1885, he secured a much greater number of Nationalist candidates for the Irish constituencies, and the firm hand with which he controlled his party was seen in the promptitude with which he crushed a revolt of Healy and Biggenden against his nomination of Captain O'Shea for Carlow.

Mr. Gladstone's views on the question of Home Rule had by this time undergone a complete change, and accordingly he introduced a Home Rule Bill, which was defeated owing to the defection of a large body of Irish Liberals, headed by Lord Hartington and Mr. Chamberlain. The consequent appeal to the country (July 1886) gave Lord Salisbury a Unionist majority of over a hundred votes, and threw Parnell into a close alliance with Mr. Gladstone and the portion of the Liberal party that adhered to him. It was at this period that the Times began to publish its series of articles entitled 'Parnellism and Crime'—a tremendous indictment against the chief nationalist leaders, the most startling point in which was a series of letters published in fac-simile, one, signed by Parnell, expressing Mr. Parnell's regret of Mr. Burke's murder. The public excitement occasioned led to the appointment of a Special Commission to inquire into the whole matter. After an elaborate trial (extending to 128 days, and closing November 22, 1889), the most sensational event in which was the break-down under cross-examination, and the flight and suicide at Madrid, of Pigott, the wretched Irishman who had imposed upon the Times with forgeries, Mr. Parnell was formally cleared of the charge of having been personally guilty of organising outrages, but his party were declared to have been guilty of incitements to intimidation, out of which had grown crimes which they had failed to denounce. Parnell now raised an action against the Times, which was quickly compromised by a payment of £2000. The 'uncrowned king' of Ireland had now reached the summit of his power—the height of the wave was marked by the presentation of the freedom of Edinburgh, July 30, 1889, and the banquet given him on his forty-fourth birthday. But his fall in public esteem was quickly to follow. A few months later his frequent mysterious absences from his parliamentary duties were explained by the news that he had married in a foreign appearance, as co-respondent in a disgraceful divorce case brought by Captain O'Shea against his wife. After formal evidence was led by the petitioner, the usual decree was granted with costs against Parnell (November 17, 1890). The Gladstone government now came to the conclusion that they must make his choice between Parnell and himself. They met and reappointed him their chairman, expecting, as the majority explained, that after his past services he would voluntarily retire at least for a time. But they had not calculated upon the characteristic obstinacy of his nature, and quickly found that their leader had no mind to efface him-
self for his country’s good. After some days of profitless and heated wrangling the majority ended the discussion by leaving the room and electing Justin McCarthy as their chairman. Parnell, with the threat that nine who claimed his name and the succession to his policy. For the great discredited and disdained leader had died suddenly at Brighton, 6th October 1891, but five months after his marriage to Mrs O’Shea. Parnell’s commanding personality might have made defeat less disastrous but to parody a writer is obviously just the strong conviction forced on Nationalists and English Home Rulers alike, that he had fatally confounded personal ambition with patriotism.

See R. Barry O’Brien’s Life of Charles Stewart Parnell (2 vols. 1890), and vol. v. of Justin McCarthy’s History of the Anti-Parnellites (1893).

Parnell, Thomas, a minor Queen Anne poet, born in Dublin in 1679, son of a commonwealth’s man who at the Restoration left Congleton in Cheshire for Ireland. He had his education at Trinity College, took orders, and in 1705 returned the Archbishopric of Cloyne, later pretented to the Archbishopric of Cashel and became a Privy Councillor. The head of an English family settled in Ireland, with property both in that country and in Cheshire, he spent much of his time in London, where his wit procured him the friendship of Harley, Swift, and Pope, and opened him the Scriblerus Club. Johnson tells us that his well-timed change of politics coincided with the election of the Whigs in the end of Queen Anne’s reign. After his wife’s death he took to drinking, and died at Chester in October 1718, while on his way to Ireland. Next year Pope published a selection of his poems, mostly translations or adaptations, with the merit at least of being ever smooth and easy in versification. The best known of his poems is the Hecat, a polished and harmonious poem, based upon Homer’s Iliad. All the rest, though as poetry, however, are the two remarkable odes, the Night-piece and the Hymn to Contentment. See the admirable Life by Goldsmith, reprinted in the Glover edition of Goldsmith’s works (1881).

Parody, a burlesque and consciously exaggerated imitation of a serious poem, the words of which should strike the ear with the very echo of the original, so that the parody is an ugly thing to pay a compliment to its popularity, and at the outset we may admit the truth of Shaftesbury’s paradox that ‘a subject which will not bear mirth may be suspected,’ provided it be not taken to mean that ridicule is to be the test of truth. The making of parodies is a harmless amusement, and moreover they may be an effective means of exposing weakness and affectation; but it must never be forgotten that, as there are, says Bacon, certain things to be privileged from jest, so there is a region of poetry into which this form of imitation may not enter. And, apart altogether from their subject, there are some poems so unapproachably beautiful in mere form and melody that to attempt a parody is a sin. Yet there are fools of such obliquity of vision and darkened understanding that they will run to the writer and the poet, and try to wring a jest out of anything. For example, Sir Charles Hanbury Williams’ Old England’s Te Deum is a form of merriment altogether to be disallowed, as are also the Mock Litanies and Visitations of Sick Parliaments of Puritan times, and those three indifferent performances of Home, mag-

nified in 1817 by the foolishness of persecution into ‘impious, profane, and scurrilous libels.’ To show any reason for its existence a parody must be very good, its subject legitimately within the range of satire, and the imitation the recognition of a well-known original, and that original neither too good to be above, nor too bad to be beneath, ridicule. Its highest end is to emphasise by the exaggeration of caricature some mannerism, or trick of metre; its surest success depends on a felicity in catching the flow of the verse, and its favourite rhythm. It is true that thoroughly to enjoy a parody must detract a little from our pleasure in the original; yet no parody will please which is not genial and human, the child at once of appreciation and knowledge. At its highest, as in Calverley, it flies from a quite unusual combination of delicacy, creative imagination, and faculty for imitation, added to a dexterous mastery of rhythms. Jeffrey, in his review of the famous Rejected Addresses, distinguishes between the mere imitation of externals and that mixture of the rarer and which brings before us the intellectual characteristics of the original. Of the latter order a diligent search has discovered but few English examples, amid the thousands of Mr Walter Hamilton’s six bulky volumes. The name parody is due to the Greeks, and the first parody, according to Aristotle, was Hegemon of Thessos, whose parody of the Gigantomachia made the Athenians forget for a moment even their disasters in Sicily. Others ascribe its origin to Hippocrates of Chios, a comic poet who flourished about 540 B.C. The well-known Butachemocamia, or Battle of the Frogs and Mice, is an ancient mock-heroic epos; and there is extant, preserved in Athenaeus, a fragment of several hundred lines by Matron, on an Attic banquet, in which each dish is introduced by a baptismic solemnity after the manner of Homer. The comedies of Aristophanes contain many subtle touches of sarcastic banter belonging more or less definitely to this order, and we find a further development in the hexameter Silli of Timon of Phlius. Among the Romans we first meet this form of derision in the comedies of Terence and the satyric scenes of Plautus. In France the burlesques of Scarron (Virgile travestir et dissous) created a taste which Boileau and others strove to counteract, and were imitated in England by Charles Cotton and John Philips in his Splendid Shilling—a vastly overrated outrage on Paradise Lost. Of modern English parodies some of the most felicitous examples are to be found in the Rejected Addresses, full of clever and genial satire unembellished by vulgarity, of which its authors could say that of the twelve poets imitated not one ever so much as the least sense or refused to join in the laugh that we are indulging. The Bon Gaultier Ballads by Ayton and Sir T. Martin, contain six admirable imitations professing to be by the unsuccessful candidates for the laureateship on the death of Sotheby. There are some excellent examples in the two classic children’s books of Lewis Carroll, but no parodies can be compared with those to be found in C. S. Calverley’s Verses and Translations and Pig Lovers. Of these it is enough merely to name ‘The Bat, the Bull, and the Ball’, and Pig Lovers, and A Reflection; as masterpieces of the art. Seven clever imitations of as many leading poets of the day, including the reputed writer himself (A. C. Swinburne), were published anonymously as The Hepatologia, or the Seven against Sense (1880). Among elaborately prose parodies most famous
are the Epistola Obscurorum Vivorum, but of these either the honour has long since evaporated, or modern men cannot now feel the merit of what drew tears of laughter from the great Erasmus. Of modern English examples may be mentioned Thackeray's 'Collingsby' on Disraeli, and 'George de Barnwell' on Lytton; Bret Harte's Condensed Novels; and F. C. Burnand's 'New Sampford and Mercer,' and 'Strapmore' on a too popular novel by Osbert.

See the article BURLESQUE; Delepherie, La Parodie chez les tires, les Romans, et les Modernes (Lond. 1871); and for a vast collection of English examples of all degrees of value, Walter Hamilton's too voluminous Parodies of the Works of English and American Authors (6 vols. 1838-89).

Parole (Fr., 'word') is the declaration made on honour by an officer, in a case in which there is no more than his sense of honour to restrain him from breaking his word. Thus, a prisoner of war may be released from actual prison on his parole that he will not go beyond certain designated limits; or he may even be allowed to return to his own country on his parole not to fight again, during the existing war, against his captors. To breach this sacred, solemn promise is not to be excused in any civilized nation, and an officer who has so far forgotten his position as a gentleman ceases to have any claim to the treatment of an honourable man, nor can he expect quarter should he again fall into the hands of the enemy he has deceived. For parole evidence, see EVIDENCE.

Parapiniasms, an ancient name still used for a ridge, less than 1000 feet above the adjacent country, which forms part of the northern edge of the great plateau of Persia and Afghanistan, almost connecting the Hindu Kush (q.v.) on the east with the Elburz Mountains to the west (see Archilochus Vol. I, p. 43).

Paros, one of the larger islands in the Cyclades division of the Greek Archipelago; a low pyramid in shape, it has an area of 64 sq. m. and a pop. of nearly 7000, of whom some 2200 live in the capital, Paravikia. Wine, figs, and wool are exported. The quarries of the famous white Parian marble are near the summit of Mount St. Elias (ancient Miropessas), and are not yet exhausted. Archilochus and Polygnotus, the painter, were born on Paros.

Parotid Gland. See Digestion and (under Saliiva) Salivary Glands.

Parquetry, a kind of wood mosaic used only for flooring. Parquetry floors are usually of oak, but other and more ornamental woods have also been much used for giving variety and beauty to the pattern. In the more elaborate kinds of parquetry veneers are used, but it is much more generally composed of blocks of wood squared at the sides, and laid down so as to combine and form a geometric pattern.

Parr. See Salmon (Vol. IX, p. 115).

Parr, CATHARINE, the sixth wife of Henry VIII., was the daughter of Sir Thomas Parr, and was born in 1512. Married first to one Edward Borough, possibly Lord Borough, and afterwards to Lord Latimer, she on July 12, 1543, became queen of England by marriage with Henry VIII. She was not only an honest and pious lady, but perhaps the most learned woman of the time, for her knowledge of religious subjects, her discussion of which with the king had well-nigh brought her to the block, like so many of her predecessors. Her tact, however, saved her: for she made it appear to the king's vanity that she had only engaged him in discussing matters not of importance in order to derive profit from his majesty's conversation. She persuaded Henry to restore the right of succession to his daughters, and interested herself on behalf of the universities. After Henry's death she married (1547) Sir Thomas Seymour, and died from the effects of child-birth in the following year.

Parr, S. AMUEL, a once notable scholar, was born the son of a surgeon at Harrow-on-the-Hill, January 15, 1741. He attended Harrow School, and, after finding unfit for apprenticeship to his father's profession, was sent to Emanuel College, Cambridge, in 1765. Two years later his father's death obliged him to leave Cambridge and accept an assistant-mastership at Harrow. Here he remained nearly five years, but, disappointed of the headship of Mr. Summer's school (1771), started an independent school at Stanmore, and kept it goving five years. He was head-master of Colchester grammar-school (1776-78) and of Norwich (1778-86). His clerical preferments were the rectory of Astley in Lincolnshire, the vicarage of Hatton near Warwick, and a prebendal stall in St. Paul's Cathedral. He spent almost the half of his life at Hatton, and here he died, March 6, 1825. The degree of LL.D. was given him by Cambridge in 1781. In 1787 he published an edition of Hellen- den, to which he prefixed his celebrated preface, which is remarkable for its uncompromising advocacy of Whig principles as for the scrupulous Ciceronianism of his Latinity.

It is almost impossible to understand the reputation which Dr. Parr once had. None of his voluminous writings justify it. That he was in some respects an accomplished scholar is undoubted, for he could write Latin of Ciceronian purity and finish; but it is equally undoubted that he never did anything with his boasted scholarship, and has left the world absolutely nothing to keep him in remembrance. Yet his complete works (edited by Sir J. A. Bulger in 1825) form eight enormous volumes, and contain 5734 octavo pages, many of them printed in small type. They relate to matters historical, critical, and metaphysical, but in all 'the thread of Parr's verbosity is finer than the staple of his argument.' To his conversational powers alone he owed the fame he enjoyed during his life. He was an amazing, an overwhelming talker. Bold, dogmatic, arrogant, with a memory profoundly and minutely retentive, and with a genuine gift of ephemeral epigram, he seemed, at the tables of statesmen, and wits, and divines, to be a man of tremendous talent, capable of any literary feat; but the learning and the repartee have left little trace of their existence, and posterity declines to admire the wonders that it has neither seen nor heard.

See E. H. Barker's ill-arranged Parame (2 vols. 1828-29), De Quincey's essay, and the Lives by Field (1828) and Johnstone (1828).

Parr, Thomas ('Old Parr'), was born, according to the tradition, in 1483 and died in 1635. See Longevity.

Parr, Parrae. See JACANA.

Parrakeet, or Parrakeet, a name very commonly given to many of the smaller species of the parrot family. The
only one we shall notice is the Zebra Parrakeet (Melopsittacus undulatus), a very beautiful little species, which has often been brought to England, and will breed in confinement. In the vast inland plains of Australia this parrakeet is to be seen in flocks of hundreds feeding on the seeds of the grasses, which afford food also to many other small species.

Parramatta, a town of New South Wales, stands on a western extension of Port Jackson, 14 miles W. of Sydney, with which it is connected both by steamer and railway. The streets are wide and regular. 'Colonial tweeds,' 'Parramatta cloths' (first from wool exported hence), beer, soap, candles, and tiles are manufactured. Much fruit, especially the orange, is grown here. Pop. (1881) 9433; (1888) 12,000. Parramatta, formerly called Rosehill, is, after Sydney, the oldest town in the colony, having been laid out in 1790.

Parrhasius, one of the greatest painters of ancient Greece, was at Athens and already distinguished among artists about the year 470 B.C. According to Xenophon, he held a conversation with Socrates, and he was a younger contemporary of Plato. Parrhasius appears to have surpassed all his predecessors in purity of design, accuracy of drawing, force of expression, and what is technically called 'finish.' And it seems that his vanity and pride were equal to his artistic skill.

Parricide (Lat. paricide) is rather a popular than a legal term. In the Roman law it comprehended every one who murdered a near relative; but in English the term is usually confined to the murderer of one's father, or of one who is in loco parentis. The parricide does not, in any respect, differ in Britain from the murderer of a stranger; in all cases the punishment is death by hanging. In the Roman law a parricide was punished in a much more severe manner, being sewed up in a leather sack, along with a live cock, viper, dog, and ape, and cast into the sea.

Parrish, Edward (1822-72), an American pharmacist, member of a family of distinguished physicians, earned his living in the drug business, and is best known through 'Parrish's Chemical Food.' This is the popular name for a non-official preparation medicinally known as Compound Syrup of Phosphate of Iron, every drachm of which contains 1 grain of phosphate of iron, 25 of saccharides and 5 of liquid. It is for children.

Parrot, the type of a large and important group of birds, divided into numerous families and genera. The parrots form an extremely compact group, showing but little structural variation, and offering no 'intermediate forms' to indicate their relationship to other birds. It has been suggested that they come nearest to the birds of prey, but this is at present no more than a suggestion. They are pre-eminently tropical birds, and arboreal in habit; some species, however, range into colder countries—e.g. Patagonia and New Zealand—and some, such as the bowing Ground Parrot of New Zealand (Strigops), now nearly exterminated by the cats run wild which infest the scrub, are not arboreal. They are fruit and seed eating birds, with the exception of the Kae (q.v.), which lays, since the colonisation of New South Wales, eggs in the nests of other birds. As a rule the parrots are brightly coloured birds, being often, like other forest-frequenting creatures, green; there are some species, however, which are not brilliantly coloured. There is occasionally the case of the two sexes, which is best marked in species belonging to the genus Eclectus; in these the prevailing colour of the female is red, and of the male green; the differences are so marked that they were actually referred to quite different genera until Dr A. B. Meyer showed conclusively that the red and green forms were merely the two sexes of the same species. The intelligence of parrots has been often commented upon, as also their power of imitating human speech; any one, however, who can endure for a sufficiently long time that pandemonium of noise, the parrot-houses at the Zoological Gardens, will find that the clearness of utterance of the Myna or Indian Starling exceeds that of any parrot. The great age to which parrots will live has often been stressed, as to 100 years, but it is at any rate certain that some species will survive for fifty years in confinement, for an individual of the Greater Vasa Parrakeet (Coracopsis vasa) lived for more than fifty years at the Zoological Gardens. Parrots make their nests in holes, and lay white eggs, as is commonly the case where the eggs are concealed. Garrod has divided the parrots, on anatomical grounds, into two families: (1) Psittacidae; (2) Psittaciformes. The Gray Parrot (Psittacus erithacus), which has been a familiar cage-bird in Europe for hundreds of years, is a native of Africa, especially of West Africa. The Great Macaw belongs to the sub-family of Coracidae, found mainly in America, one genus only (Palmarosa) occurring in India and Africa. See Dr W. T. Greene's Parrots in Captivity (3 vols. 1884).

Parrot-fish, or Parrot-wrasse (Scarus), a genus of fishes of the family Labridae. The name seems to refer to the frequently bright colours, and partly to the shape of the mouth; for the jaws form a strong and sharp beak, and the teeth are soldered together. Over a hundred species are known, especially from the tropical coral-banks, on which they browse. The most northern species (S. crenatus) is the famous Scarus, about which Greek and Roman epics were extraordinarily enthusiastic. Wonderful stories were told of its love, its wisdom, its habit of rumination, and the sounds which it makes. Pliny relates that in the reign of the Emperor Claudius a lot of Scari were brought from the Indian Ocean, released in the Italian sea, and strictly protected for five years till they became very abundant. The fish feeds chiefly on Fucus, and is certainly very palatable.

Parry, Sir William Edward, Arctic navigator, was born at Bath, 19th December 1790, entered the navy as midshipman in 1806, and saw some active service against the Danes in 1808. In 1810 he was sent to the Greenland whaling stations. Parry was one of the first to state that the Norwegian Greenland Expedition of 1819 was not undertaken to find a north-west passage. The first real attempt in this direction was made by Parry. He had two vessels under his command, Resolution and Discovery, and during his voyage he explored the whole of the western coast of North America. He was especially active in the Arctic regions and explored the west coast of North America, and the shores of the Arctic regions. Parry was knighted in 1817 and received the thanks of Parliament in 1820 for his valuable services in discovering a north-west passage.
Regent's Inlet, and Wellington Channel, and wintered in Melville Island, but his attempt in the North Pole on sleds by way of Spitsbergen was fruitless. On his return home from his second expedition he was awarded the £5000 which parliament had offered to the navigator who first crossed 110° W. long. In 1823 he was appointed hydrographer to the navy, and in 1837 was made comptroller of a department of the navy. In 1846 he retired, accepting the post of superintendent of Haslar; in 1852 he was raised to the rank of rear-admiral, and in the following year was appointed governor of Greenwich Hospital, an office which he held till his death, 8th July 1855, at Ems in Germany. A collected edition of his voyages was published in 1833 (Lond. 5 vols.). See Life by his son, Rev. Edward Parry (Oxford, 1857).

 Parsees (Pariz), 'people of Pars or Fars'—i.e. ancient Persia; sometimes called Ghuzees, q.v.—is the name coherently and commonly adhered to by the followers of the ancient Persian religion, as established or reformed by Zoroaster (Zarathustra or Zendush). The relation in which Zoroaster stood to the ancient Iranian faith and his date have been much debated; the very fact of his historical existence has even been denied; and accordingly it is difficult to dogmatise on the original principles of the Zoroastrian faith. These questions are more fully discussed under ZOROASTER and ZEND-AVESTA (see ZAND). It has been alleged that at first the doctrine was a pure Monothelism; but Zoroaster taught the existence of but one deity, the Ahura-Mazdâo (Ormuzd), the creator of all things, to whom all good things, spiritual and worldly, belong. The principle of his speculative philosophy, on the other hand, was dualism: there being in Ahura-Mazdâo two primeval causes of the real and intellectual world—the Vohu Mano, the Good Mind or Reality (Gaya), and the Aker Mano, or the Naught Mind or Non-reality (Ajañiit). Certainly, however, the pure idea of Monotheism, if it ever existed, did not long prevail. The twofold nature (Zemâla'shîn) of the supreme being is the original cause of two distinct spirits, Ahura-Mazdâo and Angra-Mainyush (Ahriman), who represented Good and Evil—God and Devil. These each took their due places in the Parsee pantheon, and Parseism became a characteristic dualism.

The Zoroastrian creed flourished up to the time of Alexander the Great, throughout ancient Iran, including Upper Tibet, Sogdiana, Bactria, Media, Persis, &c.; but after Alexander's death it gradually lost ground, rapidly declining under his successors, and under the Arsacidae was much depressed; and accordingly it is difficult to dogmatise on the original principles of the Sassanians (212 A.D.), a native Persian dynasty, by Ardashir (Artaxerxes), the first act of the new king was the general and complete restoration of the partly lost, partly forgotten beliefs of Zoroaster, which he effected, it is related, chiefly through the being chosen out of 40,000 Magi. The sacred volumes were translated out of the original Zend into the vernacular and disseminated among the people at large, and fire-temples were reared throughout the length and breadth of the land. The Magi or priests were all-powerful, and had the laws, justice, and war directed principally against the Greeks. 'Far too long,' wrote Ardashir, the king, to all the provinces of the Persian empire, 'for more than five hundred years, has the poison of Aristotle spread.' The fanatics of the priests often also found vent against the Jews, against whom they have left some account of the tyranny and oppression to which they as unbelievers were exposed—such as the prohibition of fire and light in their houses on Persian fast-days, of the slaughter of animals, the baths of purification, and the burial of the dead as burning the Jewish victims, only to be bought off by heavy bribes. In return the Magi were cardially hated by the Jews; but later we frequently find Jewish sages on terms of friendship and confidence with some of the Sassanian kings. From the period of its re-establishment by the Zoroastrians the Parsee religion spread over the western coast of India, chiefly at Bombay, Surat, Ahmedabad, and the vicinity, where they now live under English rule, and are recognised as one of the most respectable and thriving sections of the community, being for the most part merchants and landed proprietors. Parsee traders have also settled at Calcutta, Madras, Aden, Zanzibar, in Burma, and in China. They bear equally with their poorer brethren in Persia the highest character for honesty, industry, and peacefulness, while their benevolence, intelligence, and magnificence outvie that of most of their European brethren and subjects. Their general appearance is to a certain degree prepossessing, and many of their women are strikingly beautiful. In all civil matters they are subject to the laws of the country they inhabit; and its language is also theirs, except in the ritual of their religion, when Zoroastrian, or a language similar, is used by the priests, who, as a rule, however, have no more knowledge of it than the laity. They are forward to embrace the advantages of English education, and not a few have studied law in England. Conspicuous amongst Parsee merchants in Bombay are Sirkens (q.v.). In 1851 there were 80,004 Parsees in British India, of whom two-thirds of them in Bombay city.

We have spoken of the leading fundamental doctrines as laid down by their prophet. Parsees do not eat anything cooked by a person of another religion; they also object to beef and pork, especially to ham. Marriages can only be contracted with persons of their own caste and creed. Polygamy, except after nine years of sterility and consequent divorce, is forbidden. Fornication and adultery are punishable with death. Their dead are not buried, but cremated on a funeral pyre, known as Dakuma, or Tower of Silence, to the fowls of the air, to the dew, and to the sun, until the flesh has disappeared, and the bones remain under a pit beneath, from which they are afterwards removed. Above their subterranean caves.

Ahura-Mazdâo, also known by the name Surya, the origin of light, his symbol is the sun, with the moon and the planets, and in default of them the fire. Temples and altars must for ever be fed with the holy fire, brought down, according to tradition, from heaven, and the sallying of whose flame is punishable with death. The Parsee priest wears the sacred fire on his head, with a half-mask over the face, and never touches it but with holy instruments. But however great the awe felt by Parsees with respect to fire and
light (they are almost the only eastern nation who abstain from smoking), yet these people consider many of these as anything but emblems of divinity. The fires are of five kinds. There are also five kinds of 'SacriSce,' which term, however, is rather to be understood in the sense of a sacred action—in return for the slaughter of animals; prayer; the sacrifice of expiation; and (c) the presentation or (b) gifts to the priest; and, lastly, the sacrifice for the souls of the dead. The purification of physical and moral impurities is effected, in the first place, by cleansing with holy water, and, next, by prayers and the recitation of the divine word; but other self-estigations, fastings, celibacy, &c., are considered hateful to the Divinity. The ethical code may be summed up in the three words—purity of thought, of word, and of deed: a religion 'that is for all, and not for any particular nation,' as the Parsees say.

Various superstitions have in the course of the tribulations of ages and the intimacy with neighbouring countries defined the original purity of this creed, and its forms now vary much among the different communities of the present time. In the building of temples, the Parsees, as well as Conservatives and Liberals in usage, the latter allowing many innovations resisted by the others.

Parsley (Petroselinum), a genus of plants of the natural order Umbellifera. The species are annual or biennial, branching, among the most handsome plants, with variously pinnated leaves. Common Parsley (P. sativum), which has tripinnate shining leaves, one of our best known culinary plants, is a native of the south of Europe, growing chiefly on rocks and old walls, and naturalised in some parts of England. The cultivation of parsley is extremely simple, seed requiring to be sown annually in order to keep up a constant supply. A variety with curled leaflets is generally preferred to the common kind with plain leaflets, as finer and more beautiful, being often used as a garnish; it is also safer, as the poisonous Fool's Parsley (q.v.) is sometimes gathered by mistake instead of the other. Hamburg Parsley is a variety with a large white carrot-like root, cultivated for the sake of its root, and much in the same way as the carrot or parsnip. To produce large roots of and delicate flavour a very rich soil is required. The foliage of parsley is not merely of use for flavouring soups, &c., but is nutritious at the same time that it is stimulating; a quality which it seems to derive from a peculiar resin present in every part of the plant. Parsley contains also a peculiar gelatinous substance called Apioine. The bruised leaves of parsley are sometimes employed as a stimulating poultice. The seeds are a deadly poison to many birds, and when powdered they are sometimes used for killing birds.

Parsnip (Pastinaca), a genus of plants of the natural order Umbellifera, having compound umbels with neither general nor partial involucres; yellow flowers, with roundish, involute, sharp-pointed petals; calyx almost without teeth; fruit dorally compressed and flat, with a broad border, the ridges of which render it easily distinguished from parsnip, parsley, and similar species; roots fleshy, and pinnate leaves. The Common Parsnip (P. sativum) is a native of England, although not of Scotland, and is abundant in some districts, particularly in chalky and gravelly soils. It is also found in many parts of Europe and of the north of Asia. It is a biennial, with angular furrowed stem, 2 to 3 feet high, pinnate leaves with ovate leaflets, rather shining, cut and serrated, and a three-lobed terminal leaflet. The root of the wild plant is white, around the primary, fibrous, having some acidines; and injurious effects have followed from its use. Cultivation has greatly modified the qualities both of the root and foliage, rendering them much more bland. The parsnip has long been cultivated in its present form; and cultivation has greatly increased in size and become more fleshy. The flavour is disliked by some, as well as the too great sweetness, but highly relished by others; and the root of the parsnip is more nutritious than that of the carrot. The produce is also on many soils of larger quantity: and although the parsnip delights in a very open rich soil, it will succeed in clayey soils far too stiff for the carrot. It is rather remarkable that it has not been extensively cultivated as a field-crop, and for the feeding of cattle, except in the Channel Islands and in limited districts in France, and more especially in Ireland, where it is cultivated generally as cattle are very fond of it; and not only is the flesh of cattle fed on it of excellent quality, but the butter of dairy-cows fed on parsnips in winter is said by many to be superior to that produced by dairies not so supplied. The mode of cultivation of the parsnip scarcely differs from that of the carrot. There are several varieties in cultivation. A very large quantity called coquinde, cultivated in the Channel Islands on deep sandy soils, has roots sometimes 3 or 4 feet long; but this is far above the ordinary length, and there is a smaller turnip-rooted variety sometimes cultivated in gardens where the soil is very shallow. The parsnip is used chiefly in winter, whether for the table or for feeding cattle. It is improved rather than injured by frost, but is apt to become rusty if allowed to remain too long in the ground, and exhibits acid qualities after it has begun to grow again in spring. The root of the parsnip is much used in the north of Ireland for making fermented liquor with yeast and hops, and both in England and America used for that purpose. A spirit is also obtained from it similar to that of the potato. Another species, the Cut-leaved Parsnip or Sekakul (P. Sekakul), having pinnatifid cut leaflets, a native of India, Syria, and Egypt, is cultivated in the Levant, and is very similar in its uses to the common parsnip.

Parson, the incumbent of a benefice in a parish. He is called parson (Lat. persona) because he represents the church. See Clergy, DiocESART, ORDERS, PARISH, HECTOR, VICAR, Tithes, Church-Yates, Churchyard, &c. For the Parson Bird, see HONEY-BEE.

Parsons, Father Robert, the chief of the English Jesuits in their golden age, and a man of remarkable talents and achievements, was born of respectable parents in Somersetshire in 1546. When eighteen years of age he passed from the free school under Mr. John Smith, to the Manor Hall, Oxford, and after two years migrated to Balliol College, where he took his degrees of bachelor and master, and became a fellow and tutor. Here he twice took the oath abjuring the papal supremacy, but he never received the tonsure. The orders in college brought charges against him which led to his forced retirement from Oxford in 1574. He shortly afterwards became a Roman Catholic, and went to Padua with a view of there studying medicine, but, soon changing his mind, he set out on a journey to France, and joined the Society of Jesus, which he entered July 1575. He was ordained priest in 1578. When in the
following year Dr. (afterwards Cardinal) Allen, superintendent of the Donnybrook seminary, succeeded in negotiating the Jesuits to join the seminary priests in the work of the English mission, Parsons and Campion (q.v.) were selected for the new venture. They left Rome in April 1580, with strict injunctions to meddle neither directly nor indirectly in affairs of state. Parsons landed at Dover, June 11, disguised as a merchant of jewels, in a coat of buff lined with gold-lace, with hat and feather. His activity and success took both Catholics and Protestants by surprise. He employed six printers on a secret press, and by the rapid publication of tracts was successful in baffling all the attempts of the government to catch him. But soon after the apprehension of his companion, Campion, in July 1581. Parsons found it prudent to escape to the Continent, from which he never again returned to England.

Meanwhile, following the course bent of his mind, and ignoring or evading his original instructions, he had busied himself with state intrigues, sounders the political dispositions of influential Catholic laymen when treating with them of their consciences, and thought out schemes for the subjection of England to a foreign power. In Normandy, whether he at first retired, he had conferences with the Duke of Guise and with Father Creighton, who had been dispatched by the pope into Scotland to negotiate with the Duke of Lennox for the liberation of the Queen of Scots; and a little later, during April and May 1582, he was with the Provincial of the French Jesuits, the Archbishop of Glasgow, the papal nuncio, and the agent of the king of Spain, concerning a project for the invasion of England. The plan, which was chiefly the offspring of Parsons' brain, was carried through by the Duke of Guise and by Parsons himself to King Philip at Madrid. Now began his intimacy and influence with the Spanish king, and the series of political enterprises which culminated in the Armada of 1588. Affairs of state did not, however, wholly occupy the Jesuit's active mind. At Rome in 1582 he had finished his book, the Christian Directory, which has found favour with Protestant divines; and, with the aid of the Duke of Guise, he founded at Ran a seminary for youths in preparation for the colleges of Rome and of Paris. For a short time in 1582 he was rector of the college at Rome; and after the failure of the Armada he organised seminaries or clerical establishments for his countrymen at Valladolid in 1589, St. Leone in 1591, Seville and Lisbon in 1592, and at St. Omer in 1593.

In the reception which followed on the death of Allen (1593) the jealousy and suspicion with which the more loyal section of the clergy had for some time regarded the ambitious schemes of the Jesuits and the Spanish party developed into a scandalous quarrel. Disturbances broke out among the prisoners at Wisbech and in the English college at Rome. Parsons, who had just been recalled from Madrid to Rome to again assume the rectorship of the English college, now persuaded the pope to appoint George Blackwell, a partisan of the Jesuits, as archpriest over the secular clergy, with the view of keeping the chief direction of affairs political and ecclesiastical, in his own hands. The appointment was resisted by the leaders of the seculars with an animosity which threatened to create a schism. Parsons, upon whom the odium of the appointment chiefly fell, was accused of depriving the pope of tyranny over the clergy, and of continuing his enemies against his country. The stringency of the penal laws against Catholics was laid at his door. An appeal carried to Rome by four delegates of the secular clergy led to a diminution of the Jesuits' power, though Parsons persisted to the end in resisting the advances of his opponents to obtain an episcopal government. He died at Rome, as rector of the English college, April 15, 1610.

His industry and power of work were extraordinary. He wrote English forcibly and lucidly, and was a master in the arts of controversy. His dominating spirit and political partisanship created for him bitter enemies, and his relentless perseverance in pursuing his ends justly exposed him to charges of double-dealing, equivocation, and reckless slander of his opponents. He was otherwise irreproachable in his private morals. His ambition was for his order and not for himself, and he honestly desired the end and not the means. He knew on occasions to exercise tact and prudence, and, when it was his purpose to do so, no one could write with more persuasive piety. Among the best known of his voluminous publications is The Conference on the recent Succesion to the Crown, written with the assistance of Allen and Sir Francis Englefield in favour of the infant of Spain. Here he insists on the right of the people to set aside, on religions grounds, the natural heir to the throne; and avades principles which afterwards obtained for him the title of "the first English Whig." Parsons' book (35 Eliz.) made it treasonable to handle the book, which was reprinted in the interests of Cromwell in 1648. It was again reprinted in 1681, and publicly burned at Oxford in 1683. Another curious work by Parsons, for some time disseminated in manuscript only, is his Memoir for the English Nation, in which he lays down rules for the guidance of the government, in the expected event of England's subjection to the pope. The work was read at dinner-time in the English college at Valladolid when Philip was preparing another Armada. The Jesuit's mission was to inveigle the king into Renunciation and Elizabeth's citron—"a bitter libel on the queen's ministers in reply to the royal proclamation of November 1581. His Apology for the government of the archpriest (1601) is historically interesting, while his Manifestation of the Great Foley and Bud Spirit of Certain in England calling Themselves Secular Priests, a passionate attack upon the conduct and morals of his clerical brethren, exhibits him on his weakest side.

An impartial biography of this many-sided personality is still a desideratum. A brief sketch of his life and works is given by his admirer, W. G. Charlesworth, in the Dublin Review. His Correspondence (ed. W. G. Charlesworth), and a number of his letters and documents, with much miscellaneous information illustrating the whole period of his activity, are scattered through the volumes of Sir Thomas Dyer's Dodd and Mr. Foley's Records of the English Province of the S. J.

Parsonstown, or Riter, a market-town in King's County, Ireland, on the river Brosna, 89 miles by rail W. of Dublin. The castle, anciently the seat of the O'Carrols, was granted by James I. to Laurence Parsons, ancestor of the present owners, Earl of Rosse. It is a handsome, well-built town, with a statue of the Duke of Cumberland, the victor of Culloden, and a bronze statue (1870) by Foley of the Earl of Rosse, the astronomer. Pop. 4693.

Parthenogenesis (from the Gr. parthenos, 'a virgin,' and geno, 'to produce'), asexual reproduction. See GENERATIONS (ALTERNATION OF).

Parthenon (Gr., 'maiden's-chamber'), the temple of Athena (q.v.) at Athens, probably the
most perfect specimen of Greek architecture. It is a great Doric temple, erected, under the superintendence of Phidias, by Ictinos and Callicrates, of Pentelic marble, with eight pillars in the width, and fifteen at each side (not counting those at the corners). The height of the temple, from the base to the top of the pediment, was 44 feet. This magnificent relic of Periclean times stood little injured by weather or war until, when it was being used as a Turkish magazine in 1647, a bomb from a Venetian mortar burst within, and the explosion caused the building to its present ruinous condition. Illustrations will be found at Greek Architecture; a view of the ruins at Athens; and part of the frieze at Elgin Marbles, See the Dilectants Society's Athenian Architecture (1851; new ed. 1889).

Parthenonene Republic. See Naples.

Parthia, anciently a district in what is now northern Persia, lay between Media on the west and Bactria on the east, was separated from the Caspian Sea on the north by the savage land of Hyrcania, and was lengthened southward by Iranian deserts. The Parthians were of Seythian descent, immigrants and nomads, who eventually adopted the Median dress and a semi-Aryan speech. But in war they clung to their national habits: their body was loked by a horseman's coat, both man and rider were clad throughout in scale armour; their weapons were bows and arrows, which they discharged backwards during pretended flight as well as forwards in direct attack. Their armies were made up principally of slaves, commanded by theirocratic aristocratic princes of the Parthian nation. Parthia was subject successively to the Assyrians, the Medes, Persians, Greeks (Alexander the Great and his generals), and the Seleucids of Syria. In or about 250 B.C. a chief named Arsaces founded an independent kingdom in Hyrcania; his brother and successor, Tiridates, established himself in Parthia in 241 B.C. But the early kings of Parthia had much ado to maintain their position against their suzerains, the Seleucids "great kings;" and it was not until Mithridates I. (171-138) ascended the throne and had subdued Hyrcania, Media, and Babylonia, that the Parthian princes shook off completely the Syrian (Greek) voice and became independent. This king made Parthia supreme in Iran. He greatly strengthened his power by resting it in great part upon the Magi (q.v.) and by the exercise of a business policy. In the reign of his successor the Seleucid king made a determined effort to recover the lost provinces in Iran, but the expedition cost him his life and his army (129 B.C.). No sooner was this enemy disposed of than another and more formidable foe appeared in the east—the Scythians. They defeated and slew (128) the Emates, king of Parthia, levied tribute from his kingdom, and established themselves within its borders. During the first half of the 1st century the Parthian kings, by interfering in the affairs of Armenia, first came into contact with the Romans. The unprovoked invasion of Mesopotamia, by Crassus (53 B.C.), his disastrous defeat and his death, make the first act in the drama of real contest that then ensued between Rome and Parthia. The remaining acts were: the campaign of Ctesiphon by Severus (199) and his repulse before Atra (201); and the defeat of Macrinus, the Roman emperor, and his ignominious payment of fifty million denarii to his enemy (217-218). During nearly all this period the Empirates was looked upon by both combatants as the frontier line between their respective empires. The Parthian capital was Ctesiphon, a suburb or twin-capital with Seleucia, all through the duel with Rome. The Parthian empire was overthrown in a battle fought in 224 (227) A.D. by a Venetian adventurer, the Roman emperor Probus, against a province of ancient Iran, who founded the subsequent dynasty of the Sassanids (see Persia). The Parthian kings during the most flourishing period of their power used Greek as their official language, adopted Greek letters, and in other ways put themselves under the influence of Greek civilization. But the hold of this civilization grew weaker as time went on, and Greek ceased to be the official language in the 2d century A.D.

See histories of Parthia by Rawlinson (1873), Schneidewirth (Hellenismus, 1841), and Spiegel (Lepz. 1887).

Partick, a town of Lanarkshire, prettily situated, chiefly on a rising ground on the Kelvin, immediately above its junction with the Clyde, and 3 miles W.N.W. of the Cross of Glasgow, which city it now forms a suburb. Nine-tenths of the workmen of Partick are engaged in shipbuilding-yards. There are also many cotton-factories, and bleach-fields. A large proportion of the inhabitants are engaged in business in Glasgow, and for their accommodation extensive ranges of handsome villas have been built here. Partick was made a police-burgh in 1852-66. Pop. (1851) 3131; (1861) 37,411; (1871) 36,588. See Wallace's Parish of Govan (1877).

Partinico, a town of Sicily, 32 miles SW. of Palermo by rail. Pop. 21,000.

Partnership is the relation which subsists between persons carrying on business in common with a view to profit. Technically it has no reference to the relation between shareholders and a limited company. The law of partnership for the United Kingdom has been placed on a clear and intelligible footing by the Partnership Act, 1890, 53 and 54 Vict. chap. 39, which does not change the law established by decisions, but states it in an authoritative manner. Joint tenancy, or joint property, or sharing gross returns does not by itself make a man a partner. The receipt of a share of net profits is a strong indication of partnership, but it is not conclusive in such cases as a creditor, a servant or agent, the widow or child of a deceased partner, the vendor of the goodwill of a business, or the transferee of property in the way of a share in net profits. Where the person carrying on the business becomes bankrupt, however, the creditor or vendor who is paid out of profits is postponed to the other creditors. In Scotland the firm is a legal person distinct from the individual partners, but a partner may be charged on a decree against the firm, and on payment of a firm's debt is entitled to relief pro rata from the firm and the other partners. In all ordinary transactions each partner, as agent, binds the firm, unless the person dealing with the firm, knowing the partner has in fact no authority. The firm is not bound where the partner pledges his credit for a purpose apparently not connected with the business. In England and Ireland the partners are liable jointly, in Scotland severally, for firm debts. In England and Ireland if a deceased partner is subject to prior payment of separate debts. The firm is liable for the misapplication by a partner of property received by the firm, except in the case of property of which the partner is trusted when the other partner has no notice of the trust. Every person who by words or conduct holds himself out as a partner, or permits himself to be so represented by others, is liable to anybody who relied on such representations. But this will not make the executors of a deceased partner liable because the name
of the deceased has been used by the firm after his death. The assignments of a partner bind the firm, and notice of any fact to a partner is also notice to the firm, except in the case of a fraud upon the firm. A new partner does not become liable, nor does a retiring partner cease to be liable, to existing creditors. But the consent of creditors to discharge a retiring partner in respect to any account or debt of the firm and an old only debtor, is easily presumed from a course of commercial dealing. Continuing guarantees or cautionary obligations are revoked as to future transactions by any change in the constitution of the firm which is debtor or creditor. The firm is entitled to change the shares of property bought with the money of the firm is held to have been bought on account of the firm. Heritable property bought for the firm is treated as movable between partners. Unless otherwise agreed, all partners are entitled to share equally in profits and capital, and must contribute equally to losses. The firm must indemnify every partner in respect of proper payments made and liabilities undertaken by him. If a partner advances capital beyond his share, he is entitled to interest at 5 per cent. Every partner may inspect the accounts and report to his partner is entitled to remuneration for so doing.

No new partner may be introduced without the consent of all the other partners. The majority of partners cannot expel a partner. Every partner has access to the firm books. If no time has been fixed for the dissolution of the firm, any partner may at any time dissolve it by notice to his co-partners. If the partners go on trading after the time fixed for dissolution they are presumed to do so under their former agreement so far as that may be applied to a partnership at will. Every partner must account to the firm for any benefit derived by him from the partnership transaction, or any use of partnership property or business connection. The same rule applies if without consent a partner carries on a separate business competing with the firm. An assignment by a partner to his creditor of a share in the business does not operate as a discharge to the creditor as inspect books, or to require accounts, or to interfere in management, but merely to receive share of profits, or to receive the value of the share when realised on dissolution. Apart from agreement, partnership is dissolved by the death or bankruptcy of any partner, or by the business becoming unlawful. Further, the court may decree a dissolution (1) where partner is of permanently unsound mind; (2) when partner becomes permanently incapable of performing his duties; (3) when partner's conduct prejudicially affects the carrying on business; (4) when partner persistently breaks the agreement, or so conducts himself that it is not reasonably practicable for the other partners to act with him; (5) when the business can only be carried on at a loss. A person dealing with a firm after knowledge of its dissolution is entitled to treat all apparent members of the firm as still partners until he receives notice of the change. A retiring partner, not known to be a partner, is not liable for debts contracted after his retirement. After dissolution the authority of partners to bind the firm is carried for a further period not as specified—viz. in having the property of the partnership applied to payment of the debts and liabilities of the firm, and the surplus assets applied in payment of what is due to the partners after deducting what is due by the partners to the firm. If after a partner's death or retirement the other partners carry on business without any settlement of accounts, they must account for share of profits or pay interest at 5 per cent. in the option of the outgoing partner or the representatives of deceased partner. An option to purchase, however, is generally given by the contract in such cases.

In Scotland, as already stated, the firm is a distinct person. Therefore in actions by or against the firm the individual partners need not be named, though in practice one or two of them generally are named. Each partner may also sue the firm; and the firm may be sequestered without any of the partners being sequestered.

The law of the United States is based on English common law, but many of the states of the Union have their own special legislation; and, contrary to the practice of Britain, limited partnerships, resembling the French Sociétés en Commandite (see COMMANDITE), are fully recognised. On this subject the New York legislation has been generally followed; the general partners being responsible, the special partners liable only to the extent of the funds put by them into the concern. Creditors cannot directly proceed against the representatives of a deceased partner.

See Sir N. Lindley's Treatise on the Law of Partnership (6th ed. 1891), the great authority; also J. Parsons' Exposition of the Principles of Partnership (1889); F. Pollock's Digest of the Law of Partnership (4th ed. 1888); and, for the United States, Kent's Commentaries (13th ed. 1884), and Story, Law of Partnership (1851). See also the articles COMPANY, CORPORATION.

**Partridge** (*Perdix*), a genus of gallinaceous birds, of the family Tetraonidae, having a short, strong bill, naked at the base; the upper mandible convex, bent down at the tip; the wings and tail short; the tarsi as well as the toes naked, the tarsi not spurred. The Common Partridge or Gray Partridge (*P. cinerea*) is the most plentiful of all game-birds in Britain, and becomes increasingly plentiful as cultivation is extended, whilst the range of the moorowl is restricted. Hence it has greatly increased during the 10th century in Britain, and, though not preserved to the same extent as are pheasants, it affords considerable sport. It is not found in the Outer Hebrides. On the continent of Europe it is abundant in almost all districts suitable to its habits, from Scandinavia to the Mediterranean, and is found also in the north of Africa, and in some parts of the west of Asia. It varies considerably in size, those found in rich arable lands being generally the largest, and about 12 inches in entire length, whilst those which inhabit poorer and more upland districts, or where heather abounds, are rather smaller. The female is rather smaller than the male. The upper parts of both are ash gray, finely varied with brown and black; the male has a deep chestnut crescent-shaped spot on the breast, which is almost or altogether wanting in the female. A variety called the Mountain Partridge has the plumage brown. The Partridge is seldom found far from cultivated land. It feeds on grain and other seeds, insects and their larvae and pupae; and the pupae of ants.
are generally the food sought at first for the young. The nest is usually on the ground, among brushto"},null
rians of fluids, the mathematical theory of probability, and the properties of the eyeball. In the very last months of his life we find him busily engaged in a scheme for running omnibuses on the streets of Paris.

In the autumn of 1647 he returned to Paris, and we find him frequently accompanying Jacqueline in her visits to the church of Port Royal. Next year their father returned to Paris as Councillor of State, and took the pair to Clermont for nearly two years. Soon after he left Jacqueline now free to carry out her desire, joined Port Royal in the January of 1652. From some of her exaggerated phrases Pascal has been needlessly supposed to have lived a worldly life with the Duc de Roanne and other friends, and his Conversations de l'Amour has been interpreted as inspired by a hopeless passion for Charlotte Gouffier de Roanne, the duke's sister, then about sixteen years old. Certain it breathes a genuine passion throughout, and there can be little doubt that it was written out of some real experience. If Pascal did love her, it is most probable that he never told his love, for he continued to the close the warm friend and correspondent of herself and her brother alike. She ventilated awhile between the cloister and the world, passed through her novitiate at 16 and her profession at 20, and carried to the Fénalide saw her children die and her own health decay, and early sank into the grave.

In the autumn of 1654 Pascal's second conversion occurred, and from this period date those severe and gloomy austerities which darkened his life and doubtless hastened him to the grave. The immediate occasion may have been a narrow escape from death through his horses running away when driving to Neilly, but the moment that remained ever sacred in his memory was that of a remarkable vision or ecstasy, November 23, 1654, commencement of a burning, inspired devotion to the Passion of Faith, or Amulet, as Condorcet called it, which was found after his death, copied in his own handwriting both on paper and parchment, and sewn into his dioblet, being apparently stiched anew into the cloister habit that covered his body as a girdle of iron, the sharp points of which he would press into his flesh when he felt in danger from worldly temptations or wandering thoughts. For a time he lived in Port Royal, and henceforth he threw himself with a passionate devotion into its cause. Arnauld was condemned by the Sorbonne in 1653, not merely for doubting whether the famous Five Propositions condemned were actually contained in the work of Jansen, but also for asserting the identity of the Augustinian and Jansenist doctrines of gratia effectus, and for declaring that the arguments used against the Augustinians were themselves erroneous or falsified; and his friends now thought the time had come for the public to be informed about the whole question at issue.

In a happy hour Pascal was induced to lend his pen to the cause, and on the 241 January 1656, in the second volume of the first and chief work of the Sorbonne on Arnauld, appeared A Letter written to a Provincial by one of his Friends. A second was issued a few days later, and as its successors followed he assumed the pseudonym of "Lettres de M. des Jardins." These letters—the greatest tracts for the times that were ever issued—flowed from hand to hand, and the rage and fury of the Jesuits knew no bounds. Never before had been seen in the whole range of controversy such delicate yet scathing irony, such lightness of touch yet keenness of thrust, such Socratic directness and, most, such conviction of injustice of the Jesuits. "The pure grace and felicity of phrase and rare distincion of style. 'The best comedies of Molière have not more wit than the first Provinicn Letters," says Voltaire, and he adds, 'Bossuet has nothing more sublime than the concluding ones. Voltaire tells us that Bossuet himself confessed that had he not written his own, he would rather have written them than any other book he knew; even Madame de Sévigné bowed her head before their sovereign delicacy and perfection of style; Racine owned them unsurpassed in ancient or modern times; Perrault was so much impressed by their manner, and by the delicacy of language, the art of rhetoric, the exactitude of their figures, the delicate and artful rality, and Cicero's orations for strength and ingenuity of reasoning; and Gibbon tells us that almost every year he perused them with fresh pleasure, and from them learned 'to manage the weapon of grave and temperate irony, even on subjects of ecclesiastical solemnity. 'There are altogether eighteen Letters from the pen of Pascal himself, a brief fragment of a nineteenth ascribed to him, and a twentieth on the Inquisition from the pen of M. Le Maître. The two first deal with the special question between Arnauld and the Sorbonne, and this in that stirring period closely connected with these; the intervening thirteen (14-16) open up the whole subject of the moral theology of the Jesuits, and form the most formidable attack ever made upon the order. The fabric of the moral theology or cassuistry of the Jesuits, with all its subtle equivocations and refinements for the extenuation of sin, appalled the ansteure soul of Pascal as he read into it; and by the end of the tenth letter, after completing his exposition of their theology, he turns to address the Jesuit fathers directly, and breaks into language of eloquent and indeed sublime demunence. The eleventh defends the application of the method of rality to serious subjects; the twelfth and thirteenth rise to an eloquence equalled only in Democritus; the sixteenth is that the length of which he excuses because he had not had time to make it shorter. He thus ended what may be said to owed much to the materials collected in the Port Royal work, La Théologie Morale des Jésuites (1644). His quotations were confessedly often furnished for him from the wider reading of friends like Nicole and Arnauld, but he tells us that he himself had read nearly everything, and never made use of a single passage supplied to him without having specially examined it and its context. It has been charged against him that he sometimes quotes inexacty, and that he is unfair in taking quotations out of their setting, but the real grievance of his adversaries is nothing more than this, that he turns their flank by taking their own positions and developing them practically to their natural conclusions. And if it be said that he treated with too great seriousness the statements and arguments of inferior writers, it must be remembered that all these books were issued under the imprimitur of the order. At anyrate the Jesuits were much readier with denial and demunence than counter-arguments and proof; the replies of Pirot (1657), Daniel (1694), and Dumas (1709) were pitiful failures, and hardly even caused a word to be said for the Maître (in De l'Épître Gallicane, 1821) and of the Abbé Maynard's edition of the Letters with a profession refutation (1831). Pascal's own final judgment of his work was expressed in these solemn words: 'Though my Letters he condemned at Rome, what I confound in them is condemned in Heaven. Ad tuum, Domine Jesu, tribunal appello.'

Between his conversion and the beginning of his
great controversy Pascal seems to have lived chiefly at Port Royal under the spiritual guidance of M. de Scey, but he never took up his abode as a regular inmate there. His Letters occupied him till the spring of 1657, and during the following year he launched himself in a scheme for a great Apology of religion, his faith meaning with him, in the famous Miraculous Pray'r, to which, according to his niece, Marguerite Périer, a pupil at Port Royal, had been miraculously cured of an obstinate fistula lactea by a touch of a fragment of the crown of Christ. But his health was not equal to the strain, and the close he bore the burden of constant suffering with more than saintly patience and resignation. Indeed he laboured to deaden every sensation of pleasure in life, in his food, his studies, and even the affections of his friends. Meanwhile his weakness grew upon him, study and composition became possible only in brief intervals, and on 19th August 1662 he sank to rest under his sister's roof at Paris, his own house having been given up to a poor family one of whose children had been seized with smallpox.

Some years later (1699) appeared his Pensées, with a preface by Madame Périer's son—the result of the editorial labours on his fragmentary papers of a committee of influential Jansenists. Unhappily these perplexing fragments of great exactness and profundity, through external influences entirely unconnected with logic or reason, to M. Prosper Faugère belongs the honour of first giving (1844; Eng. trans. by Pearce, 1850) a complete and authentic text, although all readers will not accept his supposed discovery of the indications of an interior arrangement. Havel, in his edition (1852; 24 ed. 1866), thinks it hopeless to discover the true order, and therefore returns to Lessent's arbitrary but familiar arrangement. Victor Rochet, again (1873), adopts an elaborate arrangement, professedly founded on Pascal's own plan, and maintains that everything falls naturally into it. For these reasons the translation of 1877-79, an independent arrangement mainly on the lines of Faugère's. It is this last version which has been admirably translated into English by C. Kegan Paul (1886).

Pascal's Pensées are detached thoughts dashed rapidly off, intended as materials to be shaped into his philosophical treatise for the French faculty. They are thrilled through and through with passionate emotion and ever-present personality, and they contain some of the most profound, suggestive, and startling thoughts that have ever been expressed on the greatest mysteries within the range of human speculation. From one point of view it is easy to construct from them, as Consin did, a theory that their author was a pessimist and sceptic of a far deeper dye than Montaigne, but profounder study proves this view but a shallow paragon, at best. The conversation with De Scey first published in 1728 by Des Molets) offers the best key to Pascal's philosophy of life. Here he takes Montaigne and Epicurus as his representatives, the first of the Pyrrhonist, Epicurean, and sceptic, who mocks man's aspirations after spiritual truth upon grounds of weakness, ignorance, and doubt; the second, of the Stoic, who looks at man only on his lofty side, insists on his freedom and moral dignity, and points out in his moral nature the image and likeness of God. Pascal regards the failure of St. Paul in the great system of Christ, the overwhelming certainty of which arises out of its own affording a key to the tormenting anomalies and contradicitions of nature, at once to the moral law as revealed by conscience within and to all the disorder of the world as discovered by conscious experience—to man's greatness and man's degradation, and the reason for both the one and the other. Man's spiritual capacity alone enables him to realise his intrinsic greatness, which was first opened to him once for all when for his sake the Highest was joined to the lowest, in the incarnate union of Divine Power and Love with human degradation and pain. This is a mystery beyond man's power of demonstration, and a deeper ground for certainty must be sought in its essential correspondence with the entire nature and being of God, with the whole complex nature of man. Yet with all this there exist in the Pensées startling fragments deeply tinged with scepticism, although many of these may be interpreted with Sainte-Beuve as a kind of shorthand notes to fix ideas that flashed across his mind of difficulties to be afterwards considered. Of these none is more famous than the wager essay, in which, as has been said, and with truth, Pascal plays at pitch and toss with the existence of God and the immortality of the soul. Such a passage as this is a product, says Tulloch, of one of his terrible doubts, when the soul is so borne away on the surge of the sceptical wave that rises from the depth of all human speculation that it can only cling to the Divine by an effort of will, and with something else than a Christian's certainty, as a 'ting the winning side.' The Pensées owe much to Montaigne and Charron, and, as Molière has shown, to the 13th-century Spanish writer Raymond Martin.

The only complete editions of Pascal's works that need be mentioned are those of Bossuet (1779), LaHure (1858), and Faugère (8 vols. 1886 et seq.). Of the Provincial Letters, besides the Abbé Maynard's edition (1851) already mentioned, and M. Lesieur's reprint of the original quartos (1867), there are editions by Villemain (1829), De Sacy (1857), De Soyez (Lond. 1860), L Derome (1855 et seq.), and Molinier (2 vols. 1891). The famous Latin translation by Wendrock (Nichol.), for which he read his Terence thyrse over, appeared at Cologne as early as 1659. There are English translations by Royston (1857), Pearce (1849), and Dr M'Crie (1846). Of the Pensées there are editions from Franț, Faugère (1844, containing a considerable number of misprints and misprints, but not without good things) and Craig (1853), and Molinier (1877-79). English translations are those by Weizel, Craig, and Kegan Paul (1885). For Jacqueline Pascal's Life, see the works by Cousin (1845) and Sophy Winthrop Weizel, Sister and Saint (New York, 1888). Her miscellaneous writings, letters, and poems, together with those of Madame Périer and Marguerite Périer, were edited by Faugère (Paris, 1845).

See vols. ii. and iii. of Sainte-Beuve's Port Royal (1842-48), and Chase's ROUROL (1861); the stotre by Ruchlin (Stutt. 1840), Vinct (1856), Cousin (1857), H. Weingarten (Leipzig, 1863), Dreydorff (admireable, Leipzig, 1870), Tulloch, in 'Foreign Classics' (1878), and Joseph de Heriprand (1856). The admirable translation into English in the Edinburgh Review for January 1847 (by Henry Rogers), the Quarterly Review for October 1873, the British Quarterly Review for October 1884 (by C. Kegan Paul), and the Life and Letters in Conscientiæ for the Daily Life (1875). See also the articles Arnould, Jansen, and PORT ROYAL in this work.

Pascal. See PASSOYER, EASTER, WESTERN WEEK.

Pasca. See Herro DE PASCO.

Pas-de-Calais (Fr. for Strait of Dover), a department in the north of France, formed out of Artois and Picardy, and bounded on the W. by the Strait of Dover. Area, 2550 sq. m.; pop. (1861) 724,338; (1886) 853,526. The surface is level, with the exception of a low ridge running to the north-west, and ending in
Pasquinade, an anonymous or pseudonymous publication of small size, sometimes printed, sometimes only posted up or circulated in manuscript, and having for its object the defamation of a character, or at least the turning of a person to ridicule. The name is derived from Pasquino, a tailor remarkable for his wit and sarcastic humour, who lived in Rome towards the close of the 16th century and attracted many to his shop by his sharp and lively sayings. Some time after his death a mutilated fragment of an ancient statue, considered to represent Memenhu supporting the dead body of Patroclus, was dug up opposite his shop, and named after the tailor. It was probably a bust of Pasquino, a tutor of the Piazza Navoni. It was named after the defunct tailor, and the practice originated of affixing to it placards containing satires and jests relative to the affairs of the day—the pope and the cardinals being favourite victims of the invisible satirists. See a French monograph by Mary Lefon (2d ed. 1877).

Passage, Birds of. See Bird, Vol. II. p. 172.

Passaglia, Carlo, a Catholic theologian, was born of humble parents at Lucca. On 24 May 1580 he was trained a Jesuit, and in 1844 became professor in the Collegio Romano. He was eminent alike for his learning and eloquence. During the troubled times of 1849-51 he taught in a Jesuit college in England. In 1855 he published an elaborate treatise on the history of the Immaculate Conception; three years later he resigned his chair, and in 1859, leaving the Society of the Jesuits, entered warmly into the discussions as to the temporal power of the pope, and wrote a famous pamphlet, Pro causa Italiana de Episcopis Italianis. The result was that he had to retire to Turin, where he became Mediator and became professor of Moral Philosophy. At Turin he died, 12th March 1857.

Passaic, a city of New Jersey, on the Passaic River, 11 miles by rail NW. of Jersey City. It has foundries and print-works, and manufactures woollens and shoddy, whisk, India-rubber, chemicals, &c. Pop. (1880) 6582; (1890) 15,923; (1900) 27,777.

Passamaquoddy Bay, in North America, opens on the 13th Day of February, 1798, between the mouth of the St Croix River, between Maine and New Brunswick. It is 15 miles long by 10 wide, and shut in by a cluster of islands so as to form an excellent harbour.

Passaroilz, or more correctly POSHAREPETZ, a town of Servia, 9 miles S. of the Danube and 45 of Belgrade. Pop. 21,198. It was captured, July 21, 1718, the treaty between Venice and the emperor, on the one side, and the Porte on the other, by which a truce of twenty-five years was established, and the Banat of Temesvar, the western portion of Wallachia and Servia, Belgrade, and part of Bosnia were secured to Austria.

Passau, a town of Bavaria, stands on a rocky tongue of land, on the right bank of the Danube, beside the influx of the Inn, and opposite the confluence of the Ilz with the Danube, close to the frontier of Austria, and 72 miles by rail SE. of Ratisbon. The city proper is connected with its suburbs on the other side of the Inn and the Danube by means of iron bridges and picturesque mills encircle the whole town. The cathedral was rebuilt after a fire in 1680; the bishop's palace is now in part converted into public offices. The Passau Agreement between the Roman Catholic and Protestant estates of the empire was signed here on 29th July and 15th August 1552. Passau was a long an important fortified post, being looked upon as the key of the Danube in that part of its course. There were two strong citadels, one dating from 737, the other from 1215—19, besides other fortified works. The town grew up around an old Roman camp,
Passionists, a religious congregation of priests of the Roman Catholic Church, the object of whose institute, as indicated by their name, is to preach 'Jesus Christ and him crucified.' The founder, St. Paul of the Cross, was born in 1694 near Genoa, obtained the sanction of Benedict XIV. in 1741, and died at the mother-house of the society on the Celian Hill at Rome in 1775. The cross appears everywhere in their emblem, and a large crucifix forms part of their very striking costume. They practise many personal austerities, and their ministerial work consists chiefly in holding what are called 'missions' wherever they are invited by the local clergy, in which sermons on the passion of Christ, on sin, and on repentance, together with the hearing of confessions, hold the principal places. For a time the congregation remained in obscurity; but in the first half of the 19th century

Passenger Pigeon (Ectopistes migratorius), a species of pigeon, a native of North America. The genus to which it belongs has the head small, the bill short, the tail very long and wedge-shaped, the wings long and pointed. The male of the passenger species, generally known in North America as the Wild Pigeon, is about 16½ inches long, the tail increasing the length to 2½ inches. The color is grayish blue above, breast and sides red, dish brown, rest of the under parts white. The female is smaller and duller colored than the male. They migrate at irregular intervals in enormous flocks (of many millions at times) seeking for food, and are killed in large numbers, their flesh being dark colored, but good eating. The passenger pigeon is found throughout temperate North America.

Passeres (Lat. passer, 'sparrow'), the name given by Cuvier to the order of birds otherwise called Insessores, comprising more than half of all the birds. As the order has no well-marked characters, sparrow-like or other, common to all its members, neither name is prominent in newer classifications. See Bird, Vol. II. p. 173.

Passionflower (Passiflora), a genus of plants almost exclusively natives of the warm parts of America, and belonging to the natural order Passiacae. The flowers are hermaphrodite, with a coloured calyx, generally of five segments; the corolla also of five segments or wanting; always having a more or less conspicuous crown of filaments springing from the throat of the tube formed by the base of the calyx and corolla. The stamens are five, inserted in the tube of the calyx, united in a tube to near the apex, where they divide, and are surmounted by the much-reflexed anthers. The ovary is one-celled, elevated on a stalk, surmounted by three thick styles with thick clove-like stigmas. The fruit is fleshy. This genus has received its name from fanciful persons among the first Spanish settlers in America imagining that they saw in its flowers the emblems of our Lord's passion; the filamentous processes being taken to represent the crown of thorns, the nail-shaped styles the nails of the cross, and the five anthers the marks of the wounds. The species are mostly half-shrubby evergreen or stony climbers, of rapid growth; and most of them have lobed leaves, with from two to seven lobes. The flowers of many are large and beautiful, on which account they are often cultivated in hot-houses. Some of the species are also cultivated in tropical countries for their fruit, particularly those of which the fruit is known by the name Granadilla (q.v.). The apple-fruited Granadilla or Sweet Calabash of the West Indies is the fruit of P. maliformis, which is about two inches in diameter, containing within a hard stringy shell an agreeable gelatinous pale yellow pulp. P. quadrangularis, the common Granadilla, a native of Jamaica and South America, but is cultivated in all parts of tropical South America, and occasionally in hot-houses in Britain for the sake of its fruit. The fruit is oblong in shape, often six inches in diameter transversely. The skin when ripe is greenish yellow in color, thin, but tough and leathery, and contains a very succulent pulp of a purple color which is sweet and slightly acid. It is generally eaten with wine and sugar. The root of the plant is poisonous, owing to the presence of an active principle called passionflorine, the properties of which are similar to morphine. The laurel-leaved Granadilla is P. turutufolia, the fruit of which is named Water-lemon by the English and Pomme de Liame by the French in the West India Islands. It grows to about the size of a hen's egg, becomes yellow, dotted over with white when ripe, and contains within the tough thin rind a whitish sweet watery pulp, delicately aromatic and slightly acid. It quenches thirst, allays heat, and induces appetite. P. incarnata, a species with herbaceous stems, a native of the warm parts of South America, produces an edible orange-coloured fruit about the size of an ordinary apple. The fruit of P. editis is about two inches long and slightly less in diameter, assuming a vivid purple colour when ripe, and contains an orange-colored pulp with the flavour of a somewhat acid orange. The fruit of some species of passionflower, however, is not only unedible, but fetid; and the roots, leaves, and Passionflower (Passiflora coriacea). flowers of some have medicinal properties, narcotic, emmenagogue, anthelmintic, febrifugal, &c. The hardest species, the Blue Passionflower (P. coriacea), grows well enough in some parts of France, and even in the south of England.

Passionists, to their the known found confessions, breast 739 and leather, live greenish not M'ild colour always parts fleshy. coloured 793 but tropical edtdU all size bishopric the native n preach in<licated Coelian crucifix. of the under parts white. The female is smaller and duller colored than the male. They migrate at irregular intervals in enormous flocks (of many millions at times) seeking for food, and are killed in large numbers, their flesh being dark colored, but good eating. The passenger pigeon is found throughout temperate North America.
it rose into notice. In 1814 it secured a footing in England, where the notion had been the founder's 
spiritual aim, and in which there are now five houses; 
there are two in Ireland and one in Scotland. The 
American province, begun in 1832, numbers between 
one and two hundred religious houses. There are many 
Passionists fathers in Bulgaria and Roumania, in 
the region of Mount Athos. 

Passion Music. See ORATORIO, BACH 

Passion Play. See MYSTERIES. 

Passion-Week, the name commonly given in 
England to the week immediately preceding Easter, 
and otherwise called Holy Week (q.v.). But, by 
the proper ritual usage, Passion-Week is that 
which precedes Holy Week, commencing on Passion 
Sunday, the fifth Sunday of Lent. In the Roman 
Church and by other Christians, the first four 
weeks of Lent are also called Passion-Week, the 
solemn part of Lent, and during the succeeding 
fortnight the Glorioso Passi is omitted at the Introit, 
and all pictures, crucifixes, statues, and other 
sacred representations are veiled. 

Passive Obedience. See DIVINE RIGHT, 
DOWNS, FIFTH. 

Passover, well-known feast of the Jews. The 
English word passover is a translation of the Hebrew 
pesah, which in Aramaic with the post-positive 
article becomes pascha; whence the Greek, Latin, and 
various Romance forms of the word. The 
original meaning of the verb may perhaps be traced 
in Kings, viii, 26, where it is rendered 'leap,' 'leap on,' 'leap over,' or (revised version margin) 'leap,' and suggests a 
religious dance. The root occurs in Tishah (1 
Kings, iv, 24) or Thapascaus, an important ford or 
ferry over the Ephrates. The Passover is one of the 
oldest recurrent sacrifices of the Hebrews; an 
accusative of place is given in the prescriptive 
celebrations of it are described in 2 Chron. xxx. 
xxv, and Ezra vi.; and the laws and regulations 
relating to it will be found in Exod. xii. 1-51, xiii. 
3-10, xxii. 14-19, xxxiv. 18-26, Lev. xxvii. 4-14, 
Num. x. 1-14, xxviii. 18-25, Deut. xvi. 1-8. 
These laws were formerly held to be all practically 
contemporary pieces of legislation; but they are 
now known to be of very various dates and to 
relate to widely-different religions and social 
conditions (see PENTATEUCH). In all of them the 
Passover is intimately associated with the Feast of 
Unleavened Bread; but the latter is essentially an 
agricultural festival, and the earliest origin of the 
Passover must doubtless be sought in the times 
when the Israelites were still a purely nomadic and 
pastoral people, and gave religious expression to 
their thankfulness for the annual increase of their 
herds and flocks. It is the feast of the firstlings of 
the flock and the fatlings thereof (Gen. iv. 4). 
The recollection of such an annual festival, which 
would naturally be held in spring, survives in the 
Jehovistic narrative of the events preceding the 
exodus, which largely turned upon the refusal of 
Pharaoh to allow the people to go out into the 
wilderness to sacrifice. It was, we infer, a 
nominal lunar feast, held at the spring full 
moon, and this character it retained throughout; 
it consisted of the firstlings of the flock and of the 
fattlings of the sheep (Exod. xii. 21). 

The 17th century B.C. the victim was not necessarily a lamb 
(Deut. xvi. 2; cf. 2 Chron. xxxv. 7: 'lamb, kids, 
bullocks'). With the settlement of the Israelites 
as an agricultural people in Canaan, the agricultural 
festivals, marking the various stages of harvest and 
planting, naturally gained in importance, and the 
pastoral Passover came to be more and more 
closely associated with a harvest feast which also 
fell in spring—that of unleavened bread—when 
after the presentation of the first sheaf before 
Jehovah the people entered at once upon the enjoy-
ment of the new corn, without waiting for the 
teligious process of leavening their dough. 
The usages of the various local and domestic sanctuaries 
in the land were made uniform (Deut. xvi. 1-16) 
by the pronouncement of the law of one exclusive 
place of worship. Of subsequent modifications 
made on the Deuteronomist code by the Priestly 
legislation the most interesting perhaps are the 
stricter definition of the kind of wine offered in 
the substitution of roasting for 'boiling' (see Deut. vii. 7, 
revised version margin), and the interpolation of an 
additional day into the accompanying feast (Deut. 
xi. including the Passover in the seven days 
of unleavened bread, while Numbers xxviii. counts 
the seven days from the 15th, not the 14th, of the 
month). 

The celebration of the Passover in later times 
had public and official aspects which were 
invested occasionally at least with great pomp and 
ceremony, as may be gathered from the descriptions 
already referred to in Chronicles and Ezra; but, 
just like great ecclesiastical functions in our own 
day, it also had its private and domestic side. From 
Talmudic sources we gather a good deal that is of 
interest as to Passover customs in connection with 
public life, and they afford evidence that payment 
for a single lamb varied from ten to twenty; 
first the cup of consecration, over which the master 
of the house had pronounced a blessing, was drunk; 
then hands were washed and the meal served, 
consisting of bitter herbs, cakes of unleavened bread, 
and wine; the Passover lamb; and the seder. 
wine and vinegar, the paschal lamb, and the flesh of 
subsidiary (Deuteronomist) sacrifices. The master of 
the house dipped a morsel of unleavened bread 
into the baroshet, and ate it, and a similar 'sop' 
was given to every one present. Afterwards the 
'paschal wine' was drunk, and the unleavened 
bread was dipped in it. Thrice round the table 
was drunk at intervals with thanksgivings 
and singing of the Hallel (Psalms cxiii.-cviii.). 
To the Jews of the Dispersion the Passover, 
withgether with the Feast of Unleavened Bread, 
has always had great importance, though the lamb, 
not being slain at the Temple, is not regarded as 
strictly the paschal lamb of the law. That 
the paschal lamb typified Christ is taught 
by Paul (1 Cor. v. 7), and also by the author of 
the fourth gospel (John, xix. 36), who, as is well 
known, represents the crucifixion as having 
taken place at the time of the Passover, and attaches 
importance to the fact. 

For the history of the Passover in its bearings on Old 
Testament criticism, see Wellhausen's History of Israel 
(1885), Dr W. H. Green's Hebrew Events (New York, 1885), 
and other works cited under PENTATEUCH and HEBREW. 
For later Jewish practice, see Barthelemy's Bibliotheca 
Rabbinica or Bodenrath's Kirchliche Verfassung der Juden. 

Passow, Franz, scholar, born at Ludwigsburg in 
Mecklenburg, 20th September 1789, was educated 
at Gota and Leipzig, and in 1815 became pro-
fessor of Archaeology at Breslau, in 1828 director 
also of the museum of art there. He died 11th 
March 1833. His Handwörterbuch der griechischen 
Sprache (1819-24; 4th ed. 1841-57) is the work 
that preserves his memory, and formed the basis 
of Lübbecke and Scott's Greek Lexicon. See his Life 
by Wachsmuth, 1877. 

Passport, a warrant of protection and permis-
sion to travel, granted by the proper authority, to 
persons moving from place to place. Passports 
are sometimes issued by the ministers and consuls 
of the country which the traveller intends to visit, 
which cannot, however, be done without the con-
sent or intervention of the state in which the holder 
of the instrument is a subject; they properly pro-
cede from the authorities of the state to which 
the traveller belongs, and ought to bear the visa 
or countersignature of the minister or consul 
of the country which he is about to visit. In some
PASTEUR

European states no one is allowed to go abroad without a passport from his government authorising him to leave the country—a provision used as a means of detaining persons charged with crime; and passports are even required by the natives to enable them to go out of their own country. The regulations of different states have varied much regarding the use of passports; and of late years there has been a great relaxation of the stringency of the regulations connected with them. Sweden was the first country to give up demanding passports in time of peace; Russia and Turkey still insist on them; sometimes, as during anti-socialist excitement, German authorities demand passports from foreigners not travelling, but wishing to reside for a period of weeks in any given place; Portugal asks them of persons leaving the country by sea; and on the French and German frontiers the neighbour-governments are specially insular.

Within the United Kingdom no passports are required; but for a British subject travelling in some parts of the Continent they are still required. A British subject is entitled, however, to use passports for the purpose of enabling him to go out of the country if necessary in order to prove identity—in asking for letters at a foreign post-office, for example. At some of the German universities the production of passports and other 'papers' is required of all foreign students matriculating. The passport must usually be given up to the British subject when he visits countries other than those of the United Kingdom, as an arrangement between the governments. A passport is not required in the United Kingdom, or a certificate of identity signed by a mayor, magistrate, justice of the peace, minister of religion, physician, master of a ship, or the like, in the United Kingdom. In certain cases the production of a certificate of birth may be required. If the applicant be not personally known to the Secretary of State, he must either be recommended to him by some person who is known to him, or produce an application in his favour by some banking firm established in London or elsewhere in the United Kingdom, or a certificate of identity signed by a mayor, magistrate, justice of the peace, minister of religion, physician, master of a ship, or the like, in the United Kingdom.

Passet, a western suburb of Paris (q.v.).

Pasta, Giuditta (JUHRTII), opera singer, was born of Jewish parents, Negré by name, at Como near Milan, 9th April 1798, and received her musical education at Como and in the conservatoire at Milan. She married a singer called Pasta before 1816, and was at first a failure on the stage. Her first great triumph was achieved at Verona in 1822, seven years after she began to sing. The year following she was engaged at the Paris Italian Opera, where her singing excited great admiration. From 1825 to 1833 was the period of her most splendid triumphs, which were won principally in London and Paris. She withdrew from the stage in the following year, and resolved on the banks of Lake Como till she died on 1st April 1865. She had a magnificent voice, which passed easily from the highest soprano notes to the gravest contralto tones. In addition she possessed fine dramatic power. Her principal roles were those of Cleopatra, Semiramis, Somanambula (the opera of this name was written for her by Bellini), Nina, Camilla, and Giulia in Romeo e Giulietta.

Pasteboard. See Cardboard, Millboard, Strawboard.

Pastel, chalk mixed with other materials and various colours, and formed into Penells or Crayons (q.v.). Drawings with such dry, coloured crayons may be made on paper or parchment, and have been especially used in portraiture. Pastel is also a name for Wood (q.v.).

Pastes. See Gem.

Pasteur, Louis, distinguished for his researches in chemistry and pathology, and more precisely for many discoveries in regard to bacteria, was born on 27th December 1822, at Dôle in the department of Jura. From the college of Arbois he proceeded to the University, and thence to the Ecole of Mines and the Sorbonne in Paris. After the completion of his preparatory studies he held various academic positions at Strasbourg, Lille, and Paris, and from 1867 to 1875 was professor of Chemistry at the Sorbonne. Subsequently the centre of his work was at the Pasteur Institute in Paris. His work was at first chemical. Following up well-known researches by Arago, Blot, and Mitscherlich, Pasteur discovered the facets on tartrate crystals and what are called left-handed tartrates. He also propounded the theory that 'cold' invests chemistry—supposed to be expressed in the power which solutions of some organic substances have of causing a beam of polarised light to rotate—was characteristic of living matter and its products.

It is said that a German manufacturer of chemicals noticed that some tartrate of lime fermented when dissolved and exposed in the sun, and that this prompted Pasteur to an investigation, the result of which was the discovery of a living ferment—a micro-organism comparable in its powers to the yeast-plant which Cagniard-Latour and Schwann had discovered in alcoholic fermentation. Pasteur was further able to show that the little organism would, in a solution of paratartarate of ammonium, select for food the 'right-handed' tartrates alone, leaving the 'left-handed,' although the difference between these is merely physical not chemical. Having got hold of a clue, Pasteur went on to show that other fermentations—lactic, butyric, acetic—are essentially due to organisms. He was naturally led to corroborate and extend Schwann's researches on paratronics, which is also due to micro-organisms and this enabled him to make important practical suggestions in regard to the making of vinegar and the prevention of wine disease, as also to correct insufficiently careful experiments which were leading many to believe that spontaneous generation was demonstrable.

Prompted by his illustrious master Dumas, Pasteur next (1865) directed his inquiries to those diseases of silkworms by which the silk industry in France had been almost ruined. It is said that he had never before even seen a silkworm, though he knew the supposed disease-germs which had been demonstrated by previous investigations in the insect's blood. These he traced from egg to larva, from chrysalis to moth; and, as the pebrine disease is distinctly manifest in the adults, though it may be hidden during the pupating, there was plain that unhealthy moths should be rejected, and that all precautions should be taken to prevent infection. But Pasteur's work on the diseases of silkworms overstrained him, and in 1863 he was laid aside by paralysis. Soon, however, he was work again, investigating beer as he had investigated wine, detecting the intruders which sometimes interfere with the life of the yeast-plant and spoil the brew. His researches began to come yet closer to human life, for he discovered the splenic fever, the unction of which had been discovered by Davaine (1863), and skilfully traced from stage to stage by Koch (1876). Of Pasteur's investigations in this connection, that by which he showed that birds were not liable to fall
victims to splenic fever, because the temperature of their blood is too high for the prosperity of the germ, may serve as a characteristic illustration. Passing from splenic fever to fowl cholera, Pasteur showed that it was possible to attenuate the virulence of injurious micro-organisms by exposure to air, by the choice of a strain, or by the introduction of various animals. He thus 'tamed' the bacillus of splenic fever, and demonstrated by a memorable experiment that sheep and cows 'vaccinated' with the attenuated bacilli were protected from the evil results of a subsequent inoculation with the virulent virus. The subsequent results in regard to Hydrophobia (q.v.) are discussed in that article, contributed to this work by himself. He wrote books on most of the special researches and discoveries by which he enriched science and benefited humanity. He died 28th September 1895, and was transferred from a temporary resting-place to a tomb in the Pasteur Institute on 26th December 1896.

**Pastille**

Pasteille, usually an aromatic paste or mixture, such as *fumigating pastilles*, which are burned either as incense or as means of diffusing an agreeable odour. They are composed of charcoal powder, with such aromatic gums as benzoin, laudanum, &c., and powders of sweet-scented woods and bark gums, such as sandalwood, cinnamon, and especially cascarilla barks. Essential oils are also added, and the whole are worked into a paste with a little gum, mucilage, and formed into small sharp-pointed cones about an inch and a half high, and an inch and a half broad at the base. When they are lightly burnt they are used by lighting at the point, and as they burn down an agreeable odour is given out with the smoke. Another kind of pastille, usually in the form of a small pill covered with gold or silver leaf, is used for perfuming the breath; it is made of similar ingredients, excepting the charcoal.

**Pesto**

A town in the south-west of Columbia, in a fertile valley 8230 feet above the sea level. Above it rises the volcano of Pasto (14,000 feet above the sea); and in 1827 the town was destroyed by an earthquake. It manufactures cloth. Pop. 10,000.

**Paston Letters**

A collection of over a thousand letters and papers, mostly written by or to particular members of the Norfolk family of Paston, and the whole 15th century (1422-1569). They are of especial value as giving a glimpse into the life of England during the Wars of the Roses. The family took its name from the village of Paston, near the sea, about 20 miles N. of Norwich, and gradually grew upwards out of the condition of the smaller gentry of Norfolk. Its most famous members were William Paston, Justice of Common Pleas under Henry VI.; his son John, executor to the famous Sir John Paston; Clement Paston, a brave sailor under Henry VIII.; Sir Robert Paston, created earl of Essex 1586, and married Lady Charlotte Boyle, an illegitimate daughter of Charles II., but with him the main line and the title became extinct. It was due to the extravagance of the last that the letters were sold to Peter La Neve, from whom they passed into the hands of the Honourable Sir Thomas Pilkington, and eventually to Sir John Ferris, who edited a selection in two quarto's in 1787. The editor presented the originals of these to the king, and was knighted, but these originals have since strangely disappeared. Volumes III. and IV. followed in 1789; vol. V. posthumously, edited by Mr. Serjeant Freere, in 1823. The originals of vol. V. were dis-covered at Mr. Serjeant Freere's house at Dumgait, Cambridgeshire, in 1865; those of III. and IV. were long missing, but the whole 220 were discovered in 1875 at the family mansion of the Freeres at Boydon Hall near Dies, together with ninety-five unpublished letters of the same period, described in Mr. Gairdner's third appendix. These 311 letters were offered for sale in a London auction-room in 1888, but failed to find a purchaser at 50 guineas.

There is an admirable edition of the Paston Letters by James Gairdner in Arber's 'Annotated Reprints' (3 vols. 1872-4). It contains double as many letters as Sir John Ferris's, and, moreover, the letters are here for the first time arranged in chronological order. Mr Gairdner's answer (Fort. Reuiev. No. 11) to Herman Merivale's attack on the authenticity of the Paston Letters (Fort. Reuiev. No. 8) was completely satisfactory.

**Pastoral Epistles** See Rufe, Vol. II. p. 124; and the article TIMOTHY AND TITUS.

**Pastorals** See BASQUES.

**Pastoral Letters** A letter addressed, either at certain stated times or on the occurrence of some notable occasion, by a 'pastor,' but especially by a bishop, to the clergy under his jurisdiction, to the laity of his diocese, or to both.

**Pastoral Poetry** professes to delineate the scenes and incidents of shepherd life. As an attempt to realise an imaginary and highly idealised state of society it is a completely artificial form, and it has already disappeared from literature, never to be revived. The delightful Dorsetshire poems of Barnes exhibit the only natural method in which pastoral society can give subjects to modern poetic art. The pastorals of our modern literatures are essentially a humanistic revival of the Greek idyl of Theocritus, Bion, and Moschus, and the Latin eclogue of Virgil, and first made their appearance in Tuscany in the 16th century. The earliest dramatic pastoral is the *Favola di Orfeo* of Politian, performed at the court of Mantua in 1472, but the first complete pastoral was Agostino Becardi's comedy, Il Seruscio, played at Ferrara in 1534. Its finest and most famous successors were the *Aminta* of Tasso, represented at the court of Ferrara in 1573, and Gurrini's *Pastor Fido*. The earliest non-dramatic pastoral was G. Sannazzaro's Arcadia (1504), which through Sidney's famous romance with the same title exercised a great influence upon English literature. In Spain the pastoral flourished during the
16th century, some of the most notable names being Gil Vicente, Jorge de Montemayor (Diana, 1524), and Cervantes (Don Quixote, 1615). In France we already find Remy Belleau's Miscellany, La Bergerie (1565), and the writing of pastoral was practised long ago even by the great Richelieu. After Honore d'Urfé's Astrée (1610), came a long succession of lengthy pastoral romances by J. de Sorel, S. de Sorel, and Gomberville. In England we had already had Alexander Barclay's translations of Baptist Mantuan, and Barnaby Googe's Eglog, Epytaphes, and Sonnettes (1563), before the twelve charming elegies composing Spenser's Shepherd's Calendar (1579), formed a sound model for posterity. The poem is appropriately dedicated to Sir Philip Sidney, whose pastoral romance of Arcadia outstrips in point of literary beauty all other fictions of that class. Its successors were Robert Greene's Maucedon (1584) and Metaphon (1589), Lyly's Galathea (1584), Peele's Arraignment of Paris (1584), and, most famous of all, Lodge's Rosalynde (1590). Spenser's poetical idealisation of pastoral life, again, gave rich inspiration to Drayton, Daniel, Barnard, Marlowe, Nikital, Spenlow, Mr. Chlois, Browne, Herrick, Ben Jonson (Sud Shepherd), and Fletcher (Faithful Shepherdess, 1610), the finest of all pastoral plays. An 18th-century revival gave us the pastoral of Ambrose Philips and of Pope, and awakened a pretty quartet between the two ill-matched champions; Gay's Shepherd's Week was much better poetry than either, and was brightened by honest humour and glimpses of genuine country life. An imitator, Allan Ramsay, also achieved a success in his Gentle Shepherd, which is almost as good as Gay, though far behind Spenser.

**Pastoral Staff.** often also, although not properly, called Crosier (q.v.), one of the insignia of the episcopal office, sometimes also borne by an abbot. It is a tall staff of metal, or of wood ornamented with metal, having, at least in the Western Church, the head curved in the form of a shepherd's crook, as a symbol of the pastoral office. From an early time the pastoral staff was connected with the actual possession of the jurisdiction which it symbolises. The giving of it was one of the ceremonies of investiture; its withdrawal was part of the form of deprivation; its voluntary abandonment accompanied the act of resignation; its being broken was the most solemn form of degradation. We annex as a specimen of the highest art the pastoral staff of William of Wykeham, now preserved in his foundations, New College, Oxford. A very early form of the pastoral staff is represented at FILLAN (St.).

**Pastoral Staff.**

**Pastoral Theology,** that branch of theological science which regards the duties and obligations of pastors in relation to the souls committed to their charge.

**Pasture.** A pasture may be defined as a crop of mixed grasses and clovers, or other leguminous plants, intended for purposes of grazing. Such a crop usually occupies the land for many years, and is then called permanent pasture. The chief benefit accruing to the farmer is that the mixed plants occupy the land more completely than the same constituents grown in separate plots. The various species of the mixture overlap and foster one another; thus produce is increased, and quality of herbage improved. From this point of view, a pasture is an agricultural device for increasing the amount of land at disposal, since from a single acre of mixed crop as much produce may be obtained as from, say, ½ acre laid down under pure savings.

The chief plants used in Britain for forming pasture may be classified thus:

(A) **Top Grasses.**—Cock's-foot (Dactyliis glomerata), Meadow Fescue (Festuca pratensis), Meadow Fox-tail (Alopecurus pratensis), Timothy (Pleum pratense), Italian Ryegrass (Lolium multiflorum).

(B) **Bottom Grasses.**—Crested Dog-tail (Cynosurus cristatus), Flora (Agrostis stolonifera), Hard Fescue (Festuca durvinitidal), Rough-stalked Meadow Grass (Poa trivialis), Smooth-stalked Meadow Grass (Poa pratensis), Wood Meadow Grass (Poa nemoralis), Sweet Vernal (Anthoxanthum odoratum), Yellow Oat-grass (Avenula flavescens), Perennial Ryegrass (Lolium perenne).

(C) **Clovers and Leguminous Plants.**—Albite Clover (Trifolium hybridum), Red Clover (Trifolium pratense), White Clover (Trifolium repens), Trefoil (Medicago lupulina), Bird's-foot Trefoil (Lotus corniculatus).

This list includes several species which are not permanent, but of short duration, as Timothy, Italian and perennial ryegrass, red, and Albit clover, and trefoil. Timothy lasts from few to six years, and at times even longer. Perennial ryegrass has a very misleading name, it is much as it may die out in three or four years; in other cases, where seeding is prevented, the ryegrass may become, to all intents and purposes, a perennial plant. The reasons for including short-lived constituents in permanent pasture are obvious. They not only give increased produce during the first years of the lea, when the permanent species are slow in coming forward, but hold possession of land which would otherwise be bare, and thus keep out worthless plants. Place is made for the expanding perennials by the short-lived species which gradually die out. This must be carefully borne in mind when fixing the proportion of short-lived plants in permanent pasture.

The following are the leading principles according to which the various constituents of a mixture are proportioned: (1) To obtain maximum produce, the land must be filled with roots as thoroughly and completely as possible. This is accomplished by incorporating deep-rooted and shallow-rooted plants in due proportions. If, for example, a soil is 3 feet deep, and the roots occupy merely 1 foot of this depth, two-thirds of the land is, evidently, lying idle and unutilised, not for one year, as when under an ordinary crop, but for a long series of years in the case of a permanent pasture.

(2) The nutritive value of the mixed herbage depends upon the relative proportion of grass and clover: the albuminoid ratio increases with the amount of clover. For a permanent pasture good proportions are clovers, 20 to 30 per cent. of total area; grasses, 70 to 80 per cent.

(3) As many species as possible should be represented in the mixture. If one is injuriously affected by drought, another, which revels in drought, is required to take its place; if one is late, another is early; if one is not relished by the browsing animal, another is, and so on.

(4) Those species which are best and most suitable for the soil should be most largely represented.

(5) Certain species liable to overrun the pasture, or to destroy the clover plants, should be represented in extremely small proportions. This applies more particularly to ryegrasses (especially
PATAGONIA

I.

Italian), crested dog's-tail, and smooth-stalked meadow grass.

(6) The short-lived components should not cover more than one-third of the whole land.

According to these principles, a mixture suitable for a wet clay might be proportioned as follows:

Area of the land to be covered by clover, 20 percent:

- Red clover: 5 percent
- White clover: 5 percent

Area to be covered by short-lived grass, 20 percent:

- Timothy: 15 percent
- Perennial ryegrass: 5 percent

The percentage area of land to be occupied by each component being determined, and known, the percentage numbers have been translated into pounds of seed per acre. To get the number of pounds corresponding to these areas the covering power of each kind of seed used must be known.

We assume, as a basis for calculation, that the seed is perfect in quality—that is, the percentage of purity is 100, and the percentage of germination alike. Allowing, then, for Stihler's area of land is covered by the following amounts of perfectly pure and germinating seeds:

<table>
<thead>
<tr>
<th>Seed</th>
<th>Pounds per Acre</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hard fescue</td>
<td>10</td>
</tr>
<tr>
<td>Clover foot</td>
<td>10</td>
</tr>
<tr>
<td>White oat grass</td>
<td>7</td>
</tr>
<tr>
<td>Perennial ryegrass</td>
<td>68</td>
</tr>
<tr>
<td>Italian ryegrass</td>
<td>49</td>
</tr>
<tr>
<td>Red fescue</td>
<td>14</td>
</tr>
<tr>
<td>White</td>
<td>12</td>
</tr>
<tr>
<td>Bird's foot 5 percent</td>
<td>11</td>
</tr>
<tr>
<td>Rough stalked meadow 10%</td>
<td>13</td>
</tr>
<tr>
<td>Timothy 15 percent</td>
<td>10</td>
</tr>
</tbody>
</table>

In using these numbers as a basis for calculating mixtures, allowance must be made for seeds which cannot germinate on account of imperfect tillage, and also for the overlapping of the plants when grown in mixture. An allowance of 50 percent is found, in ordinary cases, to meet these requirements.

The amount of seed per acre actually used in mixtures is, accordingly, the amount calculated for an acre and a half.

The mixture already given for a wet clay soil when translated into pounds of perfect seed per acre (making an allowance of 50 percent) is:

- Red clover: 5 percent
- White clover: 5 percent
- Timothy: 15 percent
- Perennial ryegrass: 68 percent

By simple proportion of pounds of perfect seed can be immediately converted into pounds of commercial seed of any given quality.

Patagonia, the most southern region of the South American continent, extending from 55° S. lat. to 20° S. lat., the Strait of Magellan, which, for a distance of 375 miles, separates it from the desolate archipelago of Tierra del Fuego. Length, up to 4,000 miles; greatest breadth, about 400 miles; area, about 525,500 sq. m.; population, doubtfully estimated at about 26,000. Like the rest of the continent, Patagonia is divided by the Andes into two very unequal and dissimilar territories. South of 1831 nearly the whole coast country of the west and a strip along the southern coast. Thus the political in the main agrees with the physical partition.

Western or Chili Patagonia (63,000 sq. m.), comprising the territory of Magellan, is rugged and mountains. Along the coast, and stretch-
whole of Eastern Patagonia has probably been raised above the sea-level in the Tertiary period, and its most characteristic geological feature is its boundless expanses of shingle. The flora is in consequence exceptionally poor, and appears to be mainly derived from the lower slopes of the Andes. Herds of guanaco are numerous, and cattle are bred; pumas and foxes, armadillos, skunks, and tueutos (a peculiar rodent) are met with; and among the birds are condors, hawks, partridges, and flamingoes, ducks, and other waterfowl. But by far the most important animals are the Patagonian guanaco, which, though they are now domesticated, are expert of two hundred or more, and two species of Rhea (q.v.).

Inhabitants.—The population of Western Patagonia, estimated at 3,500 (or, including Tierra del Fuego, 4,000), consists of a number of small indigenous nomadic tribes of Araucanian stock who live by fishing and hunting, and the settlers at Punta Arenas or Magellan's colony, mainly immigrants from Chloe and other parts of Chili. In Eastern Patagonia the Argentine herdsmen are beginning to spread throughout the southern valleys, and Chilian immigrants are moving eastwards. The Patagonians proper or Tehuelche Indians, who are confined to Eastern Patagonia, are perhaps about 7,000 strong. They are generally divided into two great tribes, the northern and the southern, and their language, though the same, are distinguishable by difference of accent. The southern range chiefly over the district between the Cordilleras and the Atlantic, from the Rio Negro to the Chubut, and even the Santa Cruz River. The southern, who appear to be on an average taller and finer, and are more expert hunters, occupy the rest of Patagonia as far south as the Strait of Magellan. The two divisions are much intermixed. Magellan described the Patagonians as 'so tall that the tallest of us came up only to their waists;' and, though such extravagant statements have led others to deny the claim of the Patagonians to be considered exceptional, there is no doubt that they are one of the tallest races on the globe. The average height of the male members of Musters' party was rather over 5 feet 10 inches; that of the late Sartorius 5 feet 5 inches; of the Patagonian 4 feet each; P'llchuela, who was in Berlin in 1879, was 5 feet 9 inches high, and stretched 5 feet 11 inches with his arms. The muscular development of the arms and chest is extraordinary, and in general the body is well proportioned. The Patagonian men can walk great distances and for two and even three days on end without being tired. Their cranial characteristics are somewhat disguised by the fact that the hinder part of the skull is artificially flattened, the custom being to strap the child's head back to a board to prevent it 'wagglng' when carried about the country on horseback. This process, however, appears only to exaggerate a natural tendency; and it is asserted by the most scientific investigators that the Patagonian skull is next to that of the aborigines of the world. The jaws are powerful, though with no trace of prognathism. The expression of their face is ordinarily good-humoured though serious; their eyes are dark brown, bright and intelligent, their noses aquiline and their cheeks, thin and open and prominent. The complexion of the men, when cleansed from paint, is a reddish or rather yellowish brown. Thick flowing masses of long coarse, black, glossy hair cover their heads. The scanty natural growth of beard, moustaches, and even eyebrows, is completely eradicated. The young women are frequently well-looking, displaying healthy, ruddy cheeks when not disguised with paint. The dress of the men consists of an under-garment round the loins, a long mantle of hide with the fur inside, and boots or buskins of skin. The dress of the women is very similar. Both sexes are fond of ornaments. Besides mantles of guanaco hide, their only manufactures are saddles, bridles, stirrups, and lessos, which often evince wonderful ingenuity and nicety of execution.

The Patagonians believe in a great and good spirit who created the Indians and animals. Idols are unknown, and whatever religious acts the natives perform are prompted by dread of demons. Kindly, good-tempered, impulsive children of nature, they are apt to be recklessly bold and impetuous in taking life and limb, becoming firm friends or equally confirmed enemies. Protestant missions have been established amongst them. They are steadily decreasing through disease and bad liquor supplied by traders, and before long will be extinct. The language is quite different from either Pampa or Araucanian. Of European settlements there are few in Argentine Patagonia. The oldest, Patagonia (formerly El Carmen), on the Rio Negro, about 18 miles from its mouth, has a population of about 2000, composed of Spanish origin, who engage in trade and cowries from Buenos Ayres. There are also the Welsh colony on the Chubut (q.v.), and a petty station at the mouth of the Santa Cruz.

History.—Magellan, before passing through the strait, had in 1520 sailed along the whole of the Patagonian coast; and it is commonly believed that it was from the footsteps (patagones) observed near his winter-quarters at St. Julian that the country derived its name. Another suggested etymology is the Quichuan word patagonu, 'terraces,' which the name of the Patagonians has been traced to. The great plain was traversed by Rodrigo de Isla in 1533. Sarmiento de Gambo (commemorated by the mountain in Tierra del Fuego) added greatly to the knowledge of the west and south (1579-80), and founded Spanish settlements, doomed to early extinction, at Nombue de Dios and San Felipe (Port Famine). English interest in the country, aroused by Drake's voyage in 1577, was kept up by Davis, Narborough, Byron, Wallis, and the Jesuit Falkner, and at last the beginning of a real scientific acquaintance with the interior was made by King, Fitzroy, Darwin, and Musters. Since 1870 careful explorations have been carried out by Argentine travellers.

English works on Patagonia are Falkner's (1774), Snow's (1657), Masters' (1717), Beersbom's (1874), Lady Florence Dixie's (1878), Cook's (1879), Whitfield's (French, 1884), Burmeister (Spanish, 1891), and Fouch (Spanish, 1896).

Patan, a walled town of India, in Baroda, 64 miles N.W. from Ahmadabad, stands on a tributary of the Banas, and manufactures swords, spears, pottery, and silk and cotton goods, the capital of native dynasties from the 8th century to the present day, it has many ruins; pop. (1891) 32,646.

—Patan is also a town of Nepal, 1½ mile S.E. of Kathmandu (q.v.); Pop. 40,000.

Patanjali is the name of two celebrated authors of ancient India, who are sometimes looked upon as the same personage, but apparently for no other reason than that they bear the same name. The one is the author of the system of philosophy called Yoga (see SANSKRIT LITERATURE), the other the critic of Pāṇini (q.v.), circa 140 B.C.

Patches. During the whole of the 17th and beginning of the 18th century these fantastic ornaments were commonly worn on the knee by men. In Jack Drum's Entertainment, or the Comedie of Pasquil and Katherine (1601; 2d ed. 1616), they are thus mentioned: 'For even as blacke patches are worn, some for pride, some
PATCHOULI

1712) many of must or be Ill in such function, namely: to be liable to stamp-duty must be one which is to be used or applied externally or internally as a medicine or medicament for the prevention, cure, or relief of a disorder or complaint incident to or in any wise affecting the human body. Then it must be brought under one of the following six causes, which constitute liability to duty: (1) the seller must have or claim to have an occult secret or art for making or preparing, or (2) an exclusive right or title to making or preparing; or (3) it must have been patented; or (4) it must be, or have been, sold or used in the making or preparation of other medicines or drugs, (Lat. name, 'our') or proprietary medicine, or (5) as a specific, or (6) as beneficial for the prevention, cure, or relief of any disease. Any one of these entails liability to stamp-duty independently of the others.

All other medicines are exempt from stamp-duty: that is to say, drugs the 'decompositions,' properties, qualities, virtues, and efficacies of which are known and admitted in medicine, and in the making or preparing of which no secret art or exclusive right is claimed by any person. Instruments, medicines bottles, boxes, labels, stoppers, and similar appliances, cigarettes, preparations intended to be burned and inhaled or used as disinfectants, natural products, mineral waters, lozenges and confectionery, articles of toilet and perfumery, are all as a rule exempt from stamp-duty unless under special circumstances. The first tax on proprietary and secret medicines in Great Britain was imposed in 1783, when all persons who sold medicines and who had not been bred as doctors or apothecaries were required to take out a licence on which they paid stamp-duty, and in addition a tax on medicines imported from abroad. The duty was levied and collected on the medicine in the bottle, and the medicine was charged as such in the value of the bottle. The tax was estimated by the then Chancellor of the Exchequer that the new tax would yield £15,000 per annum. This act was amended two years later, and has been so altered by thirteen subsequent acts that none of its original provisions now remain. The patent-medicine stamp is a narrow label convenient for pasting on to a bottle or box. Such stamps are supplied by the commissioners of stamps, but for an extra payment any person may have the privilege of having stamps printed in the stamping department of Some Counties, for his own use in his own forms. The stamp affords no government guarantee of purity; its presence on any bottle or package simply signifies that the duty has been paid. The medicine must be stamped before it is sold either wholesale or retail, or for foreign or home consumption. Medicines are not considered liable to duty as long as they remain in bulk, nor are samples distributed gratis liable. The rules of duty vary from 1d. on a package not exceeding 1s., in value to £1 on a package upwards of 50s. in value. The vendors of durable medicines are required to take out a licence for his own use, at a licence fee of 5s. They pay 5s. Penalties are enforced for any infringement of the regulations. In 1860 the medicine-stamp duty yielded a revenue of £43,692; in 1870, £72,533; in 1880, £135,306; the year ending March 31, 1890, it was £217,264. See Alpe, Handy Book of Practical Chemistry for Chemistry students. Pretty beans also: the basic articles between the years 1711 and 1857, and most of these are no longer in use. Patent medicines, therefore, constitute only a very small proportion of those medicinal preparations which are liable to stamp-duty. Medicines which are so liable are those in the form of salves, ointments, plasters, collyrioins, and poultices, which are reasonably and conveniently used for the relief of such complaints as nausea, vomiting, headache, and the like.
peoples and baronetcies, appointments to judicial and administrative offices, charters of incorporation, and monopolies of the right to make, use, exercise, and vend new inventions. Of these grants it is here proposed to consider the last mentioned alone, to which the term patent is in common parlance restricted. It may, however, be observed in passing that many of these latter are privileges other than patents for inventions is still intricate and technical, resembling that which was in use for patents of invention before the Patent Law Amendment Act of 1832, and that such grants are recorded on the rolls, and may be seen at the Record Office or, in the case of its being a patent, at the Chancery Enrolment Office, London.

From a very early period in our history the sovereign has enjoyed and exercised the prerogative of securing to inventors, for a limited term, 'the sole right of making, using, and vending new and useful inventions. Thus, it is stated that Edward III., on the representation of some alchemists, granted a commission to two friars and two aldermen to inquire whether a philosopher's stone might be made, and, on their reporting that the project was practicable, granted to the inquirers a patent of privilege that they and their assignees should have the sole making of the philosopher's stone. Upon the royal prerogative, however, of which this case offers an early, though in all probability by no means the earliest, illustration, the common law placed certain definite and well-defined restrictions. (1) The sovereign could not grant the sole right to sell articles in common use. Thus, letters-patent granting to one John Peecley the sole importation of sweet wines into London were, at a parity held in the fifteenth year of the reign of Edward III., declared to be void. (2) A grant of the sole right to exercise a known occupation was bad. This was decided as to the manufacture and importation of playing-cards in the leading case of Darcey v. Allin. (3) The grantee was required to have been at least the introducer of the invention within the realm. (4) The term of the grant must be for some limited period, such as might be sufficient for the instruction of others. (5) The subject-matter must be such as, in the result, led to a new trade or manufacture. (6) The patented invention must possess the quality of utility and novelty, and must not be prejudicial or inconvenient to trade (1 Webster Patent Cases, 7 n.).

In the reign of Elizabeth, however, and still more emphatically in the reign of James I., the old common law restrictions were enlarged. The number of bond-fide inventions or discoveries was small. But the financial and political difficulties of the sovereign were great. The royal prerogative of granting limited monopolies 'for the good of the realm and the furtherance of trade' came, with many other doubtful expedients, to the sovereign's assistance. The common-law limitations were ignored. Currants, salt, iron, powder, cards, calfskin, paper, tin, sulphur, and a hundred other commodities in common use were appropriated to monopolists for practically unlimited periods. The patentee was required to disclose to the public the title and description of the patent, to be for fourteen years or under; and patents are in fact now always granted for a term of fourteen years. The grantee is to be 'the true and first inventor' of a scheme, and the patentee is not to have the benefit of the patent if a patent was granted before the true and first inventor's claim to the benefit of the patent was made, and the patent was then in use at the date of the grant, (b) not contrary to law or mischievous to the state, (c) not to the hurt of trade, or (d) not generally inconvenient. The next important measure in the history of our patent law is that of 1832. Under the common law, letters-patent were wholly void for any defect in part, not being a mere clerical error which the Master of the Rolls could correct; and a patentee was liable to be deprived of his patent from the failure of some condition, such as want of novelty in a very trifling part of the invention. The Act of 1832 enabled a patentee to enter with the clerk of patents, by permission of the crown, signed by the Chief of the law officer, a disclaimer of any part of the title or a memorandum of any alteration therein, which upon being filed by the clerk, was deemed to be part of the patent. The description of the patent, was deemed and taken to be part of the letters-patent in all courts whatever. A still more important change was introduced by the Patent Law Amendment Act, 1852. The policy of rewarding inventors, but to induce them to disclose their inventions to the public, Different means of attaining the latter object have been adopted at different stages in the history of our patent law. The earliest practice was to insert in the grant a proviso requiring the inventor and his assignees to take apprentices during the last seven years of the term, and to teach them 'the knowledge and mystery' of his invention. In the reign of Queen Anne the patentee was required within a certain period (usually six months) after obtaining his patent to enrol at one of the public record offices a specification or description of his invention, upon the accuracy and sufficiency of which the validity of his grant in great measure depended. This practice had several grave disadvantages. The record office was a place of authority, which might be altered between the grant of a patent and the enrolment of the specification enabled a patentee first to obtain protection for what might be merely
a crude idea, and then to work out its details, altering and modifying them at will, during the protected interval. The Patent Law Amendment Act of 1832 was in force in this country, and in several continental countries, and which was strongly recommended by most of the witnesses who gave evidence before the committees of 1829 and 1831, provided that a petition for the grant of letters-patent should be accompanied by a statement certifying the nature of the invention which it was sought to patent; this statement was called the provisional specification. The effect of the procedure prescribed by the act was that a patentee might use his invention for six months without prejudice to his patent rights to any other user, but if he obtained no rights against the public until his patent had been sealed. The patentee was merely protected against the consequences of his own publication, and enabled to employ workmen and obtain machinery without the risk of being betrayed.

The existing law of patents depends upon the Statute of Monopolies, the Patents Acts, 1833-38, and the Patents Rules, 1890, made by the Board of Trade under statutory authority. The present procedure to obtain a patent is as follows: An application is made by the inventor himself, and accompanied by a 'provisional specification,' in which the nature of his invention is briefly and generally described, is lodged at the Patent Office. The application and specification are then referred by the comptroller-general, who is the official head of the department, to an examiner who ascertain and reports to him whether (1) the nature of the invention has been fairly described, (2) the application, specification, and drawings, if any, have been prepared in the prescribed manner, (3) the title selected by the applicant sufficiently indicates the subject-matter of the invention, and (4) the specification does not describe more than one invention. No preliminary examination as to the novelty of the invention is held. The comptroller may, however, refuse to grant a patent for any invention of which the use would, in his opinion, be contrary to law or morality, and from such refusal no appeal can be taken. If the examiner report against the applicant on any of the grounds mentioned above, the comptroller may require the application, specification, or drawings, to be amended before he proceeds with the application. Amendments may be effected by the applicant or, if he desire, by the law officer, whose judgment is final. If, however, the examiner report in the affirmative upon each of the issues submitted to him, the application is accepted. Within nine months—a period which the comptroller may on payment of the prescribed fee extend to ten months—from the date of his application the applicant must deposit at the Patent Office a complete specification, particularly describing the nature of the invention and the best method of carrying it out. If the examiner report that the complete specification (1) does not fairly describe the invention, (2) does not contain a distinct claim or claims, (3) claims more than one invention, or (4) varies materially from the provisional, the comptroller may refuse to accept it unless and until it has been amended to his satisfaction. If the examiner refuses to accept the application, the applicant may appeal as before to the law officer, whose judgment is final. When the complete specification has been accepted it is printed and published, and the details of the applicant's invention are then for the first time thrown open to public inspection. The comptroller becomes the factotum of the patentee and has to acceptance to be advertised in the official journal of the Patent Office, and the patent is not granted until after the expiration of two months from the date of such advertisement. At any time within that period any person may oppose the grant on any one or more of the following grounds: (1) that the applicant had obtained the invention from the opponent or from some person of whom the opponent is the legal representative; (2) that the invention had been patented in this country on an application of prior date; (3) that the complete specification describes or claims an invention other than that described in the provisional, and that such other invention forms the subject of an application made by the opponent in the interval between the leaving of the provisional and the leaving of the complete specification. No other ground of opposition is recognised. The opposition is heard by a single commissioner, and any adverse decision may be appealed against to the law officer. In the event of there being no opposition, or of the opposition proving unsuccessful, the patent is issued under the seal of the Patent Office and bears the date of the original application. The term of the patent is fourteen years from its date. The grant extends to the United Kingdom and the Isle of Man, but not to the Channel Islands or to any of the British possessions or colonies. Under the Act of 1883 a patent lapses at the end of four years unless a certificate of renewal has been obtained on the payment of the fee prescribed for the purpose. The fees may be extended for keeping up a patent amount to £150. The specification or drawings relating to a patent may be amended by leave of the comptroller-general after advertising and hearing any opposition to the proposed amendment. No amendment will, however, be sanctioned the effect of which is materially to enlarge the scope of the invention originally claimed. The comptroller-general and probably the Master of the Rolls have power to correct merely clerical errors. If a patentee both fails to work his invention himself and refuses to permit other persons to do so, the Board of Trade may compel him to grant licenses upon reasonable terms.

The infringement of a patent may be restrained by injunction, and punished by damages awarded in an action at law. A patent will be revoked or, as it is termed in Scotland, reduced—if it is proved to the satisfaction of the proper court to have been obtained by fraud or false suggestion on the part of the patentee, or to lack the essential requisites of novelty and utility.

A patentee is not compelled to mark articles made under his patent with the word 'patented' or 'patented,' but any person who represents that an article sold by him is patented, when in fact no patent has been granted for the same, is liable on summary conviction to a fine not exceeding £5.

Prior to 1836 the term of a patent could only be extended by a special act of parliament (cf. Edmunds' Patents for Inventions, pp. 373-376). But the frequency of applications for statutory assistance suggested the propriety of framing some general measure for the extension or prolongation of letters-patent, and Lord Brougham's Act was passed with that view. It was intended that the public interest is now chiefly historic, followed; and section 25 of the Act of 1883 completed the legislation upon this subject. The judicial committee of the Privy-council has power to extend for a further period of seven, or in exceptional cases of fourteen, years, a patent on a satisfactorily good ground of its meritious and useful, has not adequately renumerated the patentee, from circumstances beyond his control, during the original term. It is now the practice of the judicial committee to prolong letters-patent by ordering a new grant to be made.
the country would not, therefore, support a separate profession; and the parliamentary reports of 1829 and 1851 throw somewhat painful light on the proceedings of Congress with respect to the force of the patentee with proposed W'.
The Patent Office.—All the formal, and much of the judicial, work connected with the grant of letters-patent for inventions is done at the Patent Office in Southwark Buildings, Chancery Lane, London. At the head of the whole department is an officer called the comptroller-general, who is assisted by patent agents, drawn from the ranks of the Board of Trade, and is assisted by a staff of examiners, clerks, &c. In addition to his formal and judicial duties relating to applications, the comptroller attends to the Register of Patents, in which the names of patentees and notifications of all assignments of patents are recorded and from which an annual report as to the work of the Patent Office, which is laid before both Houses of Parliament. The Patent Office contains a valuable free public library, which is ordinarily open from 10 A.M. to 10 P.M., and in which all the publications of the Patent Office—specifications, reports of cases, illustrated official journals, &c.—may be consulted.

Patents in the United States.—Before the Declaration of Independence patents were occasionally issued by the colonial governments; and the constitution of the United States contained an express power to "promote the progress of science and useful arts by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries." The Congress of 1790 passed an act regulating the issue of patents, requiring the would-be patentee to petition the Secretary of State, the Secretary of War, or the Attorney-general; with the approval of any two of these the description of the patent was certified by the Attorney-general, and the president directed the issuing of the patent. The patent was recorded in the office of the Secretary of State, and delivered to the patentee under the great seal of the United States. Under this law, which remained practically unchanged till 1836, patents were granted with little examination, and the responsibility of deciding whether the patentee had made out his case was left wholly to the courts—a system found to be inconvenient and unsatisfactory for the interests of the public. On occasion of a fire at the Patent Office, when many of the documents were destroyed, congress repealed former acts and established a new system, which remains in force till now. The general principles of the law are the same as in England, but the term for which patents are granted is seventeen years—longer than elsewhere. The Patent Office is attached to the department of the Secretary of the Interior. The commissioner, assistant commissioner, and three examiners-in-chief are appointed by the president, with the consent of the senate. The chief clerk, a staff of a hundred examiners of patents, draughtsmen, clerks, and other attendants, are nominated by the commissioner of patents and approved by the Secretary of the Interior. The office publishes pamphlets on The Patent Laws and Marks relating to the Registration of Trade-marks and Labels, and the Rules of Practice in the United States Patent Office, which may be had on application. But inventors are recommended to secure the assistance of "patent lawyers," who are a distinct branch of the legal profession. The number of patents may be exceeded, but the difficulties and references to various authorities may greatly increase the outlay. The number of patents issued in the United States greatly exceeds that of any other country. In 1837–46 the number was 5019; in 1847–50 it was 12,753; in the decade 1857–66 it was 169,476; in the century ending 10th April 1890 nearly 437,000 grants were made.
The International Convention.—It has long been the desire of inventors and legislators to bring about an assimilation of the patent laws of the world. As early as 1851 a society called the Association of American Patentees of the United States issued a list of proposed reforms in the patent law "international arrangements for a mutual recognition of the rights of inventors." Adopting in substance the views of Sir H. Bessemer, Sir William Armstrong, and others, a special committee of the American Board of Patent Commissioners, known as the American Kin-derley, the Colonial Secretary, directed the governors of the British colonies to ascertain the state of colonial opinion upon the subject. At the same time our representatives abroad were required by Lord Granville to prepare succinct reports upon the patent laws of the countries to which they were severally accredited, and these reports were published and laid before parliament in 1873 (C—741). The inquiries thus held showed that colonial and foreign official opinion was in the main favourable to the proposed reforms, particularly with regard to the agencies notwithstanding, there existed in the patent laws of the world ample materials out of which an international patent system might eventually be created. The International Congress at Vienna in 1873 and the Paris Congress, organised during the Exhibition of 1878, carried the movement forward; and on 20th March 1883 an International Convention for the Protection of Industrial Property was signed at Paris. The plenipotentiaries of the contracting parties exchanged ratifications on 6th June 1884, and the convention came into effective operation a month later. The original signatories were Belgium, Brazil, Spain, France, Guatemala, Italy, Holland, Portugal, Salvador, Servia, and Switzerland. The accession of Great Britain was delayed until special statutory power had been given to the crown to allow the antedating of patents granted under the convention. The adhesion of Great Britain to the convention took place on 17th March 1884, and was formally accepted on the 2d of April following. The United States, Norway, Turkey, Paris, New Zealand, and other countries have subsequently joined the International Union. Germany is the most important European state that still holds aloof. The principal changes introduced into our patent system by this important treaty are these: (1) Formerly a patentee could not import into some of the states now comprised in the union
articles manufactured according to his patent in this and other countries without forfeiture of his rights. Free importation of such articles without the penalty of forfeiture is now allowed. (2) An applicant for a patent in any one of the contracting states may obtain protection for the same invention by filing a simple application containing a statement of the invention and a sketch, and paying the prescribed fee within six months from the date of his foreign application. The subsequent application is ante-dated to the date of the first application, and is consequently not defeated by prior publication or user in the protected interval. The working of this provision may be best explained by a simple illustration. Suppose A, a French inventor, applies for a patent in Paris on 1st June 1890. At any time within seven months from that date he may apply to the English Patent Office to protect the same invention which he is patenting in France, and the English application, and the patent granted thereunder, are dated back to the Ist of June. The result is that A may, for almost seven months after his French application, publicly use his invention in England with perfect safety. No one can say that the patent subsequently granted is not for the same novelty, because the patent ultimately bears the date of the Ist of June, and thus protects the period during which he was using the invention in England.

In connection with the International Convention an international office or bureau has been established at Berne in Switzerland. Its expenses are defrayed by the governments of all the contracting states, and it publishes a monthly periodical entitled La Propriete Industrielle, and devoted to the interests of the union. The convention provides for conferences being held successively in one of the contracting states by delegates from the said states with a view to perfect the system of the union. The first meeting took place at Rome in April and May 1886. The number of applications at the English Patent Office for protection under the convention amounted to twenty-six in 1887 and twenty-nine in 1888.

In some countries, such as the United States of America, the Patent Office inquires strictly into the novelty and utility of every invention submitted to it for protection. In others, such as France and Turkey, there is no preliminary examination of novelty or utility. Indeed, in France the patentee, if he refers to his title at all, is obliged to add the words sans garantie du gouvernement or their initial letters, S.G.D.G. In most European states a patentee is compelled to 'work his invention in a certain time prescribed by law or limited in the grant; but this regulation or exploitation law, as it is called, is usually enforced in cases of voluntary and unjustifiable inaction alone. In the United States designs are patentable, apparently with a view to the encouragement of the decorative arts. In Switzerland, Congresses apparently cannot be patented. In Russia the patent law imposes restrictions on the patenting of inventions of war.

See Carpenter's Patent Laws of the World (1885), with its supplements, published under the auspices of the International Patent Agent; Lewis Edmunds' Law of Patents (1890); W. C. Robinson's Law of Patents (3 vols. 1890); the Reports of the Parliamentary Committees (1829-87); the Reports of the Commissioners of Patents (1837-90); and the Compendium General since 1894. See also COPYRIGHT, MONOPOLY, TRADE-MARKS.

Pater, Walter, was born in London, August 4, 1839, and educated at King's School, Canterbury, and at Queen's College, Oxford, taking a classical second-class in 1852. He was elected to an open fellowship at Brasenose; travelled in Italy, France, and Germany; and, both by his subtle critical insight and the exquisite finish of his style, earned his rank among the best prose-writers of his time. With a wise reticence he husbands his gift, hence all his work maintains the same high level of excellence. His books are Studies in the History of the Renaissance (1873), a series of essays on art and letters, on such men as Leonardo, Botticelli, Josquin des Prez, and others, written in a style infinitely modulated, with faint traces of a conscious daintiness, from which he soon shook himself free; Marius the Epicurean: his Sentiments and Ideas (2 vols. 1885), an imaginary biography of a young man brought up in Roman paganism, who passes through varied spiritual experiences, meets Marcus Aurelius himself, and at last, shortly before his unexpected death, makes acquaintance with the mysterious new eastern religion, yet without being profoundly influenced by it; Imaginary Portraits (1887) of Watteau, Denys l'Auxerrois, and others; Appreciations (1889) of Charles Lamb, Wordsworth, Coleridge, Rossetti, Sir Thomas Browne, Blake, and of Style itself; Greek Studies (1895); Miscellaneous Studies (1895) on Raphael, Pascal, North Italian art, certain French cathedrals, with some remarks on the Romanesque style; the unfinished Romance (1896). From 1885 on, Pater had a house in Kensington, and divided his time between Oxford and London. He died 30th July 1894. See Gosse's Critical Kit-Kats (1896).

Paterculus, Marcus Velleius, lived from about 19 B.C. to 31 A.D., and served as legate in the Roman provinces: HISTORICALLY. He wrote a history of universal, and more particularly of Roman history, in two books. The work, as we have it, is not complete, the beginning, and a portion following the 5th chapter, being wanting. The work is slovenly and superficial, marred moreover by interludes, all in the nature of popular and cheap fiction; as well as by fulsome flatteries of Caesar, Augustus, and Tiberius. The editio princeps appeared at Basel in 1520. Good editions are those of J. C. Orelli (1835), F. Kritz (1840-48), and C. Hahn (1876).

Patereros were small pieces of ordnance, now obsolete, worked on swivels; most commonly used on board ships, where they were mounted on the guns. They discharged small cartridges of old nails, etc., into hostile boats.

Paterno, a town of Sicily, 11 miles N.W. of Catania, at the southern base of Mount Etna. Pop. 15,230.

Pater-Noster (Lat., 'Our Father'), called also The Lord's Prayer, a short form of prayer suggested or prescribed by our Lord to his disciples (Matt. vii. 9-13; Luke, xi. 2-4) as the model according to which, in contrast with the prayers of the Pharisees, their petitions ought to be framed. The Pater-Noster has been accepted as, by excellence, the form of Christian prayer. It formed part of all the ancient liturgies, usually introduced with a preface, and said between the consecration of the elements and the communion, except the so-called Clementine liturgy, in which it does not appear at all, and the Abyssinian, in which it is said, as in the English, after the communion. St Gregory finally settled its place in the Roman Mass, immediately after the Canon and before the fraction. Whereas in the East it was said by both priest and people, in the Roman use it was recited by the priest alone. The Catechism of the Council of Trent contains a detailed exposition and commentary on our Lord's instructions, not only for the Roman Missal, Breviary, Ritual, Processional, and Orinal, but in all the occasional services prescribed from time to time, it is invariably introduced. In the Mass it is said aloud, but in the Breviary secretely, or with at most the first and concluding words said audibly. In the Rosary of the Virgin Mary it is combined
with the Hail Mary (whence the larger beads of the 'Rosary' are sometimes called *Pater-Nosters*), and perhaps the most usual of the shorter devotions among Roman Catholics is the recitation of the 'Pater Noster' or Our Father. A Missal contains all the liturgies, Roman, Mozarabic, Gallican, Greek, Coptic, and Armenian. Of the two gospels—that of Matthew and that of Luke—in which the prayer is contained, that of Luke has not this clause; and even in the gospel of Matthew it is found only in the later MSS., in which it cannot be doubted that it is a modern interpolation. It was retained, however, in Luther's German translation, in the Prayer-book (original) version, and in the English authorised version. In the revised version it is omitted both in Matthew and Luke; in Luke, 'which art in heaven,' the whole of the third petition, and 'deliver us from evil' are relegated to the margin; and in Matthew, 'deliver us from evil' is properly rendered 'deliver us from the evil one.'

Many polyglot collections of the Pater-Noster have been published; among those of the 16th century, the most remarkable of which are those of John Chamberlayne in 1590 languages (1715), of Conrad Gesner in 200 (1748), and that of Padre Hervaz in 307 (1768). There are expositions of the Lord's Prayer by Origin, Cyprian, Gregory Nyssæ, Cyprian, Lurinth, Loigten, and Tholuck. See Moses Margoliouth, *The Lord's Prayer no Adaptation of existing Jewish Petitions* (London, 1870).

**Paterson, Robert**, 'Old Mortality,' was born near Hawick in 1712 or 1715, and served his apprenticeship in a stone-mason's shop in Edinburgh with his elder brother near Lochmaben. He married soon after 1740, and, renting a quarry for himself, took to carrying gravestones into Galloway. From about 1758 he neglected to return to his wife and five children, and for upwards of forty years devoted himself to the task of repairing or erecting headstones to Covenanting martyrs, wherever such had been buried. So Joseph Train wrote to Scott, who tells how about 1800 he himself met 'Old Mortality' at Dunnotar, engaged 'in the usual business of his pilgrimage.' From the old man's account of the events Train got a different story, without a hint of Camerounian zeal. Paterson died at Bankend, 29th January 1801, and was buried at Caerlavrook, where a monument was erected to him by the Messers Black in 1809.

**See the Introduction (1830) to Old Mortality, and Dr Cowper's Tales of a Viking Fairy, and the Douglas (Dumfries, 1876).**

**Paterson, William**, the greatest commercial schemer of the 17th century, was, like Law, a Scotchman, and was born at Skipmire farm in Tinning parish, Dumfriesshire, in April 1625. His career is obscure, but it appears that, after he carried a pack through England, settled some time at Bristol, next lived in the Bahamas, whether as preacher or buccaneer, and here instated his famous Dalrien Scheme. Returning to Europe, he promoted his scheme in London, Hamburg, Amsterdam, and Berlin, made a fortune by commerce in London, founded the Hampstead Water Company in 1690, and projected the Bank of England, and was one of its first directors. In 1699, he carried the contest with Louis XIV. into the heart of Spanish America. Paterson was taken into the king's confidence, and but for his death might have seen his dreams of Dalrien realised. He had a considerable share in promoting the union of Scotland with England, and was elected to the first united parliament by the Dumfries burghs. By a special act of parliament in 1715, he was awarded £18,241 as indemnity for his losses by the Dalrien Scheme; but he did not live long to enjoy it, for he died on 22d January 1719. Paterson was no mere dreamer, but a far-seeing financier, and a free-trader before free-trade times.

See **Dalrien Scheme**; the *Life of Paterson*, by S. Bannister (1838), editor of his Works (3 vols. 1859); and W. Pagels, *Birthplace and Parentage of W. Paterson* (Edinburgh, 1850).

**Pathaus. See Afghanistan.**

**Pathology** (from the Gr. *pathos, 'disease,' and *logos, 'a discourse') is that department of medicine which treats of the doctrine of diseases, their nature, causes, symptoms, and progress. General pathology deals with disease or morbid processes in general, and special pathology with particular diseases. Pathology has also divided into internal and external, and into medical and surgical. Pathology may be treated as falling into the departments of nosology, etiology, morbid anatomy or pathological anatomy, symptomatology, and therapeutics. Humoral pathology was based on the theory that all diseases were due to the disordered condition of the humours and fluids of the body. Cellular pathology, associated with the name of Virchow, gives prominence to the action of cells in the healthy and diseased functions of the body. See also ANATOMY, DISEASE, MEDICINE, PATHOLOGY, and the articles on the several diseases in this work; also works on pathology by Wilks and Moxon (1875), Wagner (Eng. trans. 1876), Coats (1833), Delaheld and Prudden (New York, 1885), Cornil and Jirras (trans. W. J. Kees, 1885), Ziegler (trans. 1882-96), Payne (1888), Hamilton (1889), Rindfleisch (trans. 1885), Sutton (1886).

**Patiala**, a native state in the Punjab, India, partly in the plain south of the Sutlej, partly amongst the hills near Simla. Pop. (1891) 1,683,521; area, 5,887 sq. m. The capital, also called Patiala, has a pop. of 189,955, 806.

**Patkul. See CHARLES XII.**

**Patmore, Coventry.** Keary Deighton, poet, was born at Woodford in Essex, July 23, 1823, the son of P. G. Patmore, author of * Literary Reminiscences*. He published a volume of *Poems* in 1844, and three years later joined the staff of the *British Museum*, where he remained till 1868, when he purchased a small estate in Sussex. Soon after he settled at Hastings, where he built a large Catholic church. His second volume of poems, *Tamerton Church-tower*, &c. (1853), prepared the way for his greatest work, *The Betrothal*. It is an elaborate, exquisite, and sincere poem of love from the domestic side, which has had a great popularity, but not beyond its deserts. It consists of four parts, all included under the general title for the first time in the edition of 1866: *The Betrothal*...
PATMOS (1854), The Exponents (1856), Faithful for Ever (1860), and The Victories of Love (1863). A carefully revised edition of this poem was issued in his collected poems (1878 and 1886), with an essay on English Metrical Law, and including The Unknown Erros, a mystical poem first published in 1877. The Rod, the Root, and the Flower (1865) contains religious poems. Patmore edited the anthology entitled The Children's Garland (1862), the Autobiography of Barry Cornwall (1877), and the poems of his son Henry (1884).

Florilegium Antiquum was a collection from his poems (ed. Garnett, 1888); another was Poems of Patmos and Delight (ed. Meynell, 1893). He died 26th November 1896.

Patmos (or Patino), a rocky island in the Aegean Sea, one of the Sporades, lies to the south of Samos; area 16 sq. m. In a cave here, it is said, the exiled apostle John saw the visions of the Book of Revelation. The famous monastery of 'John the Divine' was built in 1898. The island is under Turkish rule, but is inhabited by about 4000 Greeks, mostly sponge-fishers. See Tower, Islands of the Aegean (1890); and the Minutes of the Scottish Church, v. 103.

Patna, called also Azimabad, a city of Bengal, 140 miles E. of numares by rail, extends 9 miles along the Ganges and 2 miles back from the river; but the streets are narrow and crooked, and the houses mostly mean in appearance. Apart from the Gola or government granary (1786), the government opium factories, Patna College, and the shrine of Shah Arzana, the mosque of Sher Shah, a Roman Catholic church, and a Mohammedan college, there are no buildings of moment. Its railway communication, and its central position at the junction of three great rivers, the Son, the Gandak, and the Ganges, attended by the use of the Ganges and Patna sections of the North-west Provinces, render Patna of great importance as a commercial centre. The chief imports are cotton goods, oil-seeds, salt, sugar, wheat, and other cereals; they reach an annual value of nearly 4 million sterling. The exports, principally oil-seeds and salt, with cotton, spices, English piece-goods, cacao nuts, and tobacco, exceed 61 million sterling in value. Patna, under its early name of Patiliputra, is supposed to have been founded about 600 B.C. It was visited by Megasthenes, the Greek historian, about 300 B.C., and called Patalipura by him. In modern times Patna is notable as the residence of nine British prisoners by Mir Kasim in 1763, which led to war and annexation by the English, and for the mutiny at Dinapur, the military station of Patna, in 1857. Patna ranks as fifteenth city of India in point of population; pop. (1872) 138,000; (1891) 165,192. - The district has an area of 2079 sq. m., and a pop. of about 1,800,000; the division, an area of 23,724 sq. m., and a pop. of 16,000,000.

Patna, a native state of the Central Provinces, India; area, 2969 sq. m.; pop. about 275,000. It has been under the management of a British political agent since 1871. Patna, the chief town, has a pop. of 2053.

Patris, the French term for dialects of a language spoken especially by the uneducated. See Dialect.

Patron, John Gibson, missionary to the New Hebrides, the son of a stocking-maker, was born in the parish of Kirkmahoe, Dumfriesshire, 21st May 1824. After some experience in Glasgow Cur. Mission, he offered his services for the foreign mission field in connection with the Reformed Presbyterian Church, and on his ordination he settled down towards the end of 1858 amongst the cannibal natives of Tanna. Here he laboured amidst trials and difficulties till 1862, when he was forced to leave, owing to the hostility of the natives.

For the next twenty years his work was on the neighbouring island of Aniwa, the whole population of which became Christian. Both by voice and pen he afterwards attracted public attention and sympathy towards this field of mission labour; and his lecture and his graphic and thrilling missionary narratives, 1st and 2nd series (1890). In 1891 he was made a D.D. of Edinburgh.

Paton, Sir Noel, painter, was born in Dunfermline, 13th December 1821, and studied for a time at the Royal Academy, London. His cartoon sketch, 'The Spirit in the Wilderness' gained one of the three premiums at the Westminster Hall competition in 1845. Two years thereafter his oil-picture of 'Christ bearing the Cross' and his 'Reconciliation of Obecon and Titania', jointly gained the price of £300. The latter and its companion picture, 'The Quarrel of Obecon and Titania', are now in the National Gallery at Edinburgh.

'Dante Meditating the Epistles of Francesco' was exhibited in Edinburgh in 1852; the 'Dead Lady' in 1854; and 'The Pursuit of Pleasure' in 1855. Scenes from fairyland and from ancient legend, and religious and mystical allegory, are depicted by him with rare grace, atmosphere, and sentiment. As a result of over-restraint, have made his work familiar, and have been often engraved. Among his other pictures are 'Home from the Crimes'; 'In Memoriam', a scene from the Indian Mutiny; a series of six picture-illustrations of the 'Bawbee Deene o' Yarrow'; 'Lather at Erfurt'; 'The Fairy Raid'; 'Faith and Reason'; 'Gheshemane'; 'Christ and Mary at the Sepulchre'; 'The Man of Sorrows'; 'Mors Janna Vite'; 'The Spirit of Twilight'; 'Thy Will be Done' (1873); 'Beati Mundo Corde' (1881). He has also illustrated A. B. Scott's 'Scenes from the Life of St Columba', and in 1864 he executed twenty illustrations of the Ancient Mariner. He is an R.S.A., was appointed Queen's Limner for Scotland in 1863, received the honour of knighthood in 1867, and in 1876 was made an L.D. of Edinburgh.

He has published two volumes of poems.

Patra or Patre, a fortified seaport town and the most important in the west of Greece, climbs up a hillside and spreads out at its foot on the eastern shore of the Gulf of Patras, by nil 81 miles W. by N. of Corinth and 137 W. by N. of Athens. It is a handsome city, having been almost entirely rebuilt after the great fire of 1821. It is defended by a citadel, the seat of an archbishop, and has a spacious new harbour (1880) protected by a mole. It ships great quantities of currants, chiefly to Great Britain and France, the former taking from 50,000 to 60,000 and the latter from 18,000 to 28,000 tons annually. Besides currants, olive-oil, wine, valonia, &c. are exported. The imports embrace chiefly woollen and cotton goods, iron, machinery, coal. British ships import goods to the annual value of £246,400, and carry away exports to £1,173,000. Pop. (1879) 13,694; (1891) 14,970. It is the site of the 'twelve cities' of Achaea which still exists as a town; but most of its relics have been swept away by earthquake (551, 1820) and siege (by the Spaniards in 1382 and 1593, by the Knights of St John in 1693, and by the Greeks, 1822-28). It was an archbishop sees of Christianity, having an archbishop before 347.

Patria Potestas. See Family, Parent and Child.

Patriarch (Gr. patriarches, 'the head of a tribe') is the name given to the heads of the families in the antediluvian period of Scripture history, and is still more familiar as the designation in Jewish history of the three progenitors of the Jewish people, Abraham, Isaac, and Jacob.
In the later history of the Jews, too, after the destruction of Jerusalem, the Greek name was used to designate the heads of the college which was regarded as a continuation of the old Sanhedrim; one of whom, the patriarch of the west, resided at Tiberias, in Galilee, and the other, the patriarch of the Eastern Jews, at Babylon. The patriarch of Tiberias was also regarded by the Roman imperial government as the metropolitan of the Jews of Palestine. The most familiar use of the word, however, is in the history of the Christian church. It is the name given to the bishops of certain great metropolitan sees, who not only held rank beyond other metropolitans, but also possessed an ecclesiastical jurisdiction over the bishops of other sees and over the clergy of pagans which were subject to their jurisdiction. The patriarchs included in their district almost identical with that of the metropolitan in his own province. It is certain that the name and the office were both recognized before the Council of Nice, at which time, as we learn from the sixth canon, the patriarch sees, according to an ancient custom, were three in number, Rome, Antioch, and Alexandria. After the translation of the seat of empire to Byzantium, thenceforth called Constantinople, that see, originally subject to the metropolitan of Jerusalem, was elevated to the rank of a metropolis, and eventually established a precedence over the patriarchs of Antioch and Alexandria, being second only to Rome. The contests between the patriarchs of Rome and Constantinople were among the chief causes of the Greek Schism. To these four patriarchates was allotted a fifth in the year 451, that of Jerusalem, which was formed out of the ancient patriarchate of Antioch. The limits of these five patriarchates can only be loosely assigned. After the Greek Schism, and particularly after the establishment of the Latin Kingdom of Jerusalem, Latin prelates were appointed with the title and rank of patriarch in the four great Eastern sees resident at Rome; in 1847 the Latin patriarch took up his residence in Jerusalem. The Catholic Church also recognizes Maronite, Melchite, and Syrian patriarchs of Antioch, an Armenian see of Cilicia, a 'Coptic Patriarch of Babylon. There are also minor patriarchs of Venice, of Spain, and of the Indies. For the patriarchs of the Orthodox Eastern Church, see Greek Church.

Patrick (Lat. patris, from pater, 'father'), a name given to the members of Roman gens of whom the populus Romanus originally consisted, and to persons imitating these by adoption. On the establishment of the plebeians as a distinct order, sharing certain rights with the patricians, the patriciate became an aristocracy of birth, in the exclusive possession of a number of important privileges. A long struggle between the two orders ended in the attainment by the plebeians of a political equality, and the establishment of a new aristocracy of nobles based on wealth and position (see Nobility, Rome). Under Constantine the dignity of patres became a personal title; not granted by law, but conferred very high honours and certain privileges. The popes in after times conferred the same title on eminent persons and princes; and elsewhere also the title of patrician was bestowed on distinguished subjects.

Patrick, St., a distinguished missionary of the 5th century, commonly known as the Apostle of Ireland. There is much uncertainty as to the date and place of his birth. His birth is assigned to the year 372 by Ussher (Eccles. Brit. Antiq., in vi. pp. 375-380, with which compare Wh. Stokes's Introduction to Tripartite Life of St Patrick, p. xxxvi., Rolls series, Lond. 1897). Of the place, it is only known for certain, from his own Confession, that his father had a small farm near Bannavem Taberniae; and in one of the ancient lives he is said to have been born at Nenagh. Arguing on these data, together with other collateral indications, some writers place him at Antrim, a place to the present Boulogne-sur-Mer; others to a place on the estuary of the Clyde (called from him Kilpatrick) near Dunbarton. His father, as he himself tells, was a deacon named Calpurnius, and his grandmother was a Palladius, a priest; his mother, according to the ancient biographers, was named Conches or Concessa, and was a sister of St Martin of Tours. Patrick's original Celtic name is said to have been Suoec, Patricius being his Latin designation. In his sixteenth year he was seized, while at school, by the Irish king and made a member of a band of pirates, and with a number of others was carried to Ireland and sold to a petty chief, in whose service he remained for six years. This chief's name was Milicue or Milehn. He lived in the valley of the Braid near Sleemish Mountain, just outside the town of Broughshane, in the centre of the County Antrim, where a 'town-land called Bally-lig-patrick ('the town of Patrick's hollow') still preserves the memory of his residence. This district of Antrim was then famous for its piratical expeditions, and the news of the capture of the Alexandrian patriarch eventuated in Patrick's flight from Dalriada, which was the residence of John Cassian, the abbot of the famous monastery of Lérins, which was then the residence of John Cassian, the abbot of the Egyptian monastery of Luxor, and of vast numbers of Egyptian monks; hence the numerous points of contact with the Egyptian customs which have been noticed in the ancient Irish Church (see Ireland, Vol. vi. p. 210, and 361, p. 211, p. 211, p. 211, p. 211). T. Stoneman, A Coptic Church, and Coptic Churches, passim). In the year 432 he went as a missionary to Ireland when sixty years of age, after he had been ordained by an unknown Gallic bishop named Matorix or Amatorix, or else by Germanus of Auxerre; Palladius, who had been sent by Pope Celestine as missionary to that country a short time before, having died. He seems to have been made a bishop in his forty-fifth year.

The leading facts of Patrick's life in Ireland as they are collected out of the various documents are these. He landed from France in the year 432. He made the Welsh claim that he landed in Wales before he went to Ireland (see Gibrals Cambrensis, iii. 379, Rolls series). The communication, however, between Wales and the east coast of Ireland has been very frequent from the earliest ages. He first landed as a missionary in Ireland at the town of Wicklow at the mouth of the river Vartry; thence he sailed north to convert his old master Milehn, who destroyed himself at his approach. Milehn was a chief of Northern Dalriada, a district which extended from the middle of Antrim to Newry. In the County Down, in the south of the same Dalriada, he converted another chief named Dichu, who bestowed upon him the first Christian church that St Patrick possessed. It was called Sallaball (Saul) or 'the barn,' and it still a church called by exactly the same name. St Patrick then set out to Tara in the County Meath, which was at that period the central point of meeting for all the tribes of Ireland. There he met and to the king of Tara, Loegaire, or Leary (as the name should be pronounced), where he preached the doctrine of the Trinity; this is, however, a mere modern legend. Thence he proceeded to Connaught, as far as Craigh-Patrick in Mayo, to Ulster, and as far as Cashel in the south. We can trace his mission all through the country, his utterance the topography of the country as well as the documents which are extant. His mission was eminently
successful. He adopted the expedient of addressing himself first to the chiefs, and of improving, as far as possible, the spirit of chivalry and other existing usages of the Irish for the furtherance of his preaching; nor can it be doubted that he had much success. He was the first to introduce the Catholic system of belief and of practice. According to the accounts of his Irish biographers, he founded 365 churches and baptised with his own hand 12,900 persons. He is said also to have consecrated 550 bishops, ordained a vast number of priests, and having divided the island into parishes, he transmitted to them his own works. After he had been some twenty years engaged in his missionary enterprise, he is said to have fixed his seat in Armagh about the year 454, where he held probably more than one synod, the decrees of which have been a subject of much controversy. He died at Sami, the spot where Dhu had given him on his first arrival, and was buried at Downpatrick, where his relics were preserved down to the period of the Reformation. The place is still venerated by the people. The date of his death is much disputed, the Hibernians placing it in 460, while Ussher holds it to have been 453. Dr. Todd inclines strongly to the latter opinion, in which case Patrick's age would have been quite 120. The only certainly authentic literary remains of St. Patrick are his "Confession" and a letter, both of very rude Latin, but of much historical interest. The letter is addressed to Constantine, by some supposed to have been a Welsh chiefman named Caradoc (from whom Caridian is named), by others regarded as a pirate chief from near Dumbarton (W. Stokes, "Tripartite Life of St. Patrick," Intro. p. c.), who had made a descent on the west coast, and slain the inhabitants with circumstances of great cruelty, a number of the Irish, many of whom were nephews. These, with some other remains ascribed to him, as also decrees of synods, were published in Wilkins' "Concilium," and separately by Ware, "Opera S. Patrick," 1830. The life of St. Patrick is in MS. in Trinity College, Dublin, dating from the 8th century. The copy in it of St. Patrick's Confession claims to have been made from St. Patrick's autograph. For this MS., see Stokes' "Celtic Church." A good biography of St. Patrick is that of the Rev. J. Smith, "Life of St. Patrick," 1852; a general one is by E. J. Newell (1890). The best and latest edition of all the documents concerning St Patrick is Dr. Whitley Stokes's two vols. in the Rolls series (1887) styled the "Early Church in Ireland." Patrick, the historical figure and bearing upon his history has been industriously gathered and critically estimated. Dr. Whitley Stokes has there printed the documents from the Book of Armagh which are the earliest authentic notices of the saint, and the foundation upon which all later lives have been built.

Patrick, Simon, a learned English divine, born at Gainsborough in Lincolnshire, 8th September 1626, was educated at Queen's College, Cambridge, and was successively rector of St Paul's, Covent Garden (1662), where he laboured heroically through the horrors of the Great Plague, Dean of Peterborough (1678), Bishop of Chichester (1689) and of London (1701). He died on May 31, 1707. He was a theologian no less devout than erudite, an ecclesiastical of wide sympathies and large sagacity, he established a solid reputation by his excellent sermons, of which may be selected for special mention that preached at the funeral of John Smith of Candover. He was a Discoursed with, as his admirable if sometimes prolix devotional and expository treatises, some of which are still read; and his sound and frequently reprinted paraphrases and commentaries on the historical and poetical books of Scripture from Genesis to Canticles (10 vols. 1695-1710). Of the expository works may here merely be named A Brief Exposition of the Ten Commandments and the Lord's Prayer, The Parable of the Pilgrims, The Heart's Ease, The Christian Sacrifice, Advice to a Friend, The Devout Christian Instructed, and Jesus and the Resurrection justified. His Autobiography was first printed at Oxford in 1683, and enlarged in the complete Oxford Clarendon Press edition of his works, edited by the Rev. Alexander Taylor (9 vols. 1858).

Patrick, The Most Illustrious Order of St., a national order of knighthood for Ireland, established by George III. on the 5th of February 1783, and enlarged in 1833. It now consists of the Grand Master, the Grand-Sovereign, the Grand-Master, and twenty-two Knights. The Collar of the order (of gold) is composed of roses alternating with harps, tied together with a knot of gold, the roses being enamelled with a centre of white within red, and red within white; and in the centre is an imperial crowned star, holding a harp of gold, from which the badge is suspended. The Badge or Jewel is of gold, and oval; surrounding it is a wreath of shamrock proper on a gold field; within this is a band of sky-blue enamel charged with the motto of the order, Quis Separabit MIGLOXIII, in gold letters; at the point of this band a sinister gules (the cross of St. Patrick), surmounted by a shamrock or trefoil slipped vert, having on each of its leaves an imperial crown or. The field of the cross is either argent or pierced and left open. A sky-blue Ribbon, worn over the right shoulder, sustains the badge when the collar is not worn. The Star, worn on the left side, differs from the badge only in being circular in place of oval, and in substituting for the exterior wreath of shamrocks eight rays of silver, four of which are larger than the other four. The order is indicated by the initials K.P.

Patripassians. Lat. pater, 'father, and passus, 'suffered'), a name given to one of the earliest churches of anti-Trinitarian sectaries (2d century), who, in maintaining the oneness of the Godhead, were said by their enemies to believe that, as it was true to say that Jesus, in whom dwelt the Logos, or the Son, suffered, therefore it would be true to say that the Father suffered. Their principles are in the main the same with those of the Sabellians (q.v.).

Patristic Literature. See FATHERS OF THE CHURCH, and separate articles.

Patroclus. See Achilles.

Patron (Lat. patronus, from pater, 'father'), among the Romans originally signified a citizen who had dependents, who were called clients, attached to him. Before the time of the Laws of the Twelve Tables, the most frequent use of the term patronus was in opposition to libertus, these
two words being used to signify persons who stood to another in the relation of master and manumitted slave. Of these latter, in part from the manumitter of slaves continued to exist. A Roman citizen, desirous of a protector, might attach himself to a patron, whose client he thence-forward became; the patron was the guardian of his client's personal, public and private; as his legal adviser he vindicated his client before the courts of law. The client was bound on various occasions to assist the patron with money, as by paying the costs of his suits, contributing to the marriage portions of his daughters, and defraying in some instances the expenses of discharge of public functions (see ROME). As the patron was in the habit of appearing in support of his clients in courts of justice, the word patronus acquired in course of time the signification of advocate or legal adviser and defender, the client being the party defended. Patron in after times became a common designation of every protector or powerful promoter of the interests of another; and the saints who were believed to watch over the interests of particular persons, places, trades, &c. acquired in the middle ages the designation of their patron saints.

The term Patron has also been applied to those who endowed or supported churches and convents. The question of ecclesiastical patronage, or the right of the patron to present to livings, is dealt with in BISHOP OF CANTERBURY, SOCIETY OF PaterSON-BONAPARTE. See Bonaparte, Vol. II. p. 288.

Patteson, John Coleridge, the martyr-bishop, was born in London on 1st April 1827, the son of Sir John Patteson, judge in the Queen's Bench, and of a niece of Coleridge the poet. He passed through Eton and Balliol College, Oxford, and was elected a Fellow of Merton in 1822, and in the following year appointed curate of Allington, near Ottery St Mary, in Devonshire. But his thoughts soon turned to missionary work, and in 1835 he sailed with Bishop Selwyn of New Zealand. The next sixteen years he spent amongst the Maoris in New Zealand, on the Solomons, and Loyalties; and in 1846 he was consecrated Bishop of Melanesia. An unselfish man and a true Christian, he was greatly beloved by the islanders, whom he likewise loved and faithfully tended over, protecting them to his utmost against the white kidnapers, and the Pacific cruiser was killed by the natives of Nukapu, one of the Santa Cruz group, on 20th September 1871, it is believed in revenge for relatives carried away by the white 'slavers.' See Life by Miss Yonge (2 vols. 1874).

Patti, Adelina, prima donna, was born at Madrid, 19th February 1843, the daughter of a Sicilian tenor and the 'Signora Barilli,' a Roman. At seven she sang 'Casta Diva' in Tripli Hall, New York; and in the same city she made her operatic début as 'Lucin' in 1859. In London she first appeared in 1861 as 'Amina' in La Sonnambula, when her success was so splendid as to lead to a European tour, and the course of her career wherever she has sung—Paris, St Petersburg, both the Americas, &c. In Russia, in 1870, she received from the emperor the Order of Merit. Her voice is an unusually high soprano, reaching to E flat, of rich bell-like tone and remarkable evenness; to these qualities she adds a certain spirit of style and the highest artistic finish. Equally at home in the tenderness of deep passion and the sprightly vivacity of comedy, she has also sung splendidly in oratorio. She married in 1866 the Marquis de Caux, and, on her divorce from him, the tenor Ernesto Nicolini (1834-98). Her home is Craig-y-nos Castle, near Swansea.—Her elder sister, Carlotta, born at Florence in 1840, was likewise a very fine vocalist, though a slight lame- ness prevented her from appearing in opera. She made her début at New York as a contralto singer in 1861, married in 1879 the cellist Ernst de Munck, and died at Paris, 28th June 1889. See Engel's From Mozart to Mario (1886).

Pattison, Mark, scholar, was born in 1813 at Hornby, Yorkshire, but brought up mostly at Haughw, of which parish his father had become rector. The eldest of twelve children, of whom ten were daughters, he grew up amid the Yorkshire moors, with a close knowledge of nature and a love for field-sports, which in the one case he shared with his father till the last. He was educated at home until he entered Oriel College at Oxford in 1832. A shy and awkward lad, diffident and hesitating, without the wholesome discipline of public school life, he suffered much in his first years as an undergraduate, but his sufferings were the fruit of his own lack of self-reliance, his morbid self-consciousness, and hyper-sensitiveness of temperament. He took his bachelor's degree in 1857 with a secondclass in classics, and was elected Fellow of Lincoln College in the same year. Under the dominant influence of Newman he gave himself first to the study of theology, twice (1841-42) carried off the Denyer prize, wrote two Lives of the Saints, translated for the 'Library of the Fathers' the Matthew in the Catena Aurea of Aquinas, and almost followed his master into the fold of Rome, but escaped only, as he himself explains, by his habits of study and a constitutional slowness to act. Fortunately we have his own account of his spiritual growth, out of the Puritanism of his home into the wider atmosphere of Anglicanism, and how that in its turn fell from the hands of the Church, and the Catholic Church opened itself up before his eyes, only to disappear before the highest development, when all religions appear in their historical light as efforts of the human spirit to come to an understanding, standing with that Unseen Power whose presence it feels, but whose motives are a riddle. His reaction from Newmanism: reawakened within him all his zeal for pure scholarship, and, no less lofty in his ideal of the teacher than the student, he soon became a tutor of altogether exceptional devotion and extraordinary success, and at the end of his college life he was made sub-rector, under the aged Dr Tatham. On the death of the latter in 1851 Pattison was kept out of the headship which was his right by a disinherited obscurantist intrigué, which gave an almost paralyzing blow to his sensitive nature. A further unsuccessful attempt was made to deprive him of his fellowship on the technical plea that he had not proceeded in time to the degree of B.D., and the result of his disappointment was that for seven years he took little real interest in the life of Oxford, yet, when he came to himself, he henceforth grew rather towards an increase of the professorial than the tutorial system. But his educational sympathies soon extended far beyond mere college life; he published an article on education in the Oxford Essays, acted as assistant-commissioner on the Duke of Newcastle's Commission of Inquiry into Elementary Education in Germany, rambled in the long vacations through England, Scotland, and Germany, visiting most of the universities of the latter country, and served for three months in 1856 as Commissioner to Berlin. Meanwhile he gave himself with rare devotion to severe and unbroken study, and scholars soon came to recognise his Roman hand in the columns of the Quarterly, the Westminster, and the Saturday Review. His humble and thoughtful Report on Elementary Education in Protestant
Germany appeared in 1859; his equally learned and temperate paper on "Tendencies of Religious Thought in England, 1688-1759," in Essays and Reviews (1861), is a notable example of the essay. Rector, but, though he made an exemplary head, the spring and elasticity of earlier days were gone. In 1862 he married the accomplished Emilie Frances Strong, afterwards Lady Dilke, who helped him to make Lincoln a social and intellectual centre for a world-wide renaissance (1866). Oxford. Down to his last illness and his death at Harrogate, 30th July 1884, he lived wholly for study, maintaining a medieval rather than modern ideal of the life of the scholar as a sufficient end in itself.

Everything Mark Pattison wrote has characteristic: nowhere else among contemporaries could be found such fullness of knowledge and earnestness of thought, shaped ever into terse and vigorous English. Yet his standard of perfection was so high that his actual achievement is far more suggestive than demonstrative of his powers, and the greatest project of his life—the study of Seallger—remains a fragment, printed by Professor Nettle-

ship in vol. i. of Pattison's collected Essays (1889).

Besides the books already named he published Suggestions on Ecclesiastical Organization (1868); advices on Smallpox at the time of Smallpox Acts (1869) and Satires and Epistles (1870); Jose Caucaubon, 1659-1714 (1875), which grew out of his Seallger studies; Milton, almost the best book in the 'English Men of Letters' series (1879); the Sonnets of Milton (1883); and Sermons (1885). His position at Oxford as his brother, a strikingly frank judgment of himself and others—even his own father—and a remarkable revelation of a singular moral and intellectual personality, describing, without restraint, the whole current of his thoughts and feelings from 1832 to 1869. 

Excerpt from the biography of Henry Paley. His sister was born at Hauxwell, January 16, 1832, the youngest but one of her father's family. She grew up amid her native Yorkshire moors a handsome and healthy girl of remarkable humour, spirit, and vigour, and had her young enthusiasm kindled by the heroic devotion of Florence Nightingale. In October 1861, against the advice of all her family, she started a life of labour for others as schoolmistress at Little Woodston, near Hitchley, and in the autumn of 1864 joined the sisterhood of the Good Samaritan, near Huncow, near Doncaster. Here 'Sister Dora,' underwent severe discipline, but found subject in devoted labours as a nurse, first at North Ormesby, near Middlesbrough, and in 1865 at Walsall. Ere long she gave herself entirely to hospital work, and her absolute self-forgetfulness, patience, gentleness, and skill quickly brought her the adoration of the saint from the rough men and women for whom she spent her strength. In 1874 she left the Good Samaritan Community, and in 1877 took charge of the municipal epidemic hospital at Walsall, where the cases were mainly of all sorts of venereal diseases. She also frequently offered her services on behalf of unfortunate women, and did much for her poor neighbours in every way. But even her strength at last gave way, and she died a true martyr for Christ's sake at Walsall, December 24, 1878. The whole population of the town followed the body to the grave, and the working-men erected a monument to her memory in 1880.

See Sister Dora: A Biography, by Margaret Lonsdale (1890)—which Mark Patison, with a characteristic touch, coin's Miss Lona's tale of romance. Tolleman's Recollections of Pattison (1895).

Pau, the chief town of the French department of Basse-Pyrénées, on the right bank of the Gave
de-Pau, 66 miles by rail ESE of Bayonne and 143 SSE of Bordeaux. It occupies a rocky height, 633 feet above sea-level, and commands towards the south most magnificent views of the serrated Pyrenees; indeed, for mountain scenery its situation is more in the nature of a Picturesque than that of the ancient capital of the kingdom of Béarn and French Navarre, it has a noble five-towered castle, rising to a height of 110 feet. Rebuilt about 1363 by Gaston Phlous, Comte de Foix, and restored by Louis-Philippe and Napoleon III., this castle was the birthplace of Henri IV., as also of his mother Jeanne d'Albret; and Abel-el-Kuder was a prisoner here in 1484. Bernadotte was likewise a native of Pau, which, beyond a statute of King Henri (1843), has nothing else calling for notice. Linen and woollen stuffs are its chief manufactures; and in the vicinity Jurassic wine (good but strong) is made, and many wines are sold, whose port supplies the famous 'Jambons de Bayonne.' Pau is a great English resort, especially during the winter season (October to May), and is famous for its golf-links. Pop. (1872) 25,307; (1891) 31,111. See Count Henry be zeall, Pau, Bearrrs, and the Pyrenees (new ed. 1891).

Pauillac, a port on the left bank of the estuary of the Gironde in France, 30 miles N. by W. of Bordeaux by rail, is the place from which the best brands of Méece (claret) are shipped to Bordeaux. Pop. 22,100.

Paul. It is probable that no man ever swayed the religious opinions and destinies of mankind so powerfully as Paul of Tarsus, the Apostle of the Gentiles. He was greater than some of the greater presbyters than Chrysostom, a greater missionary than St Francis Xavier, a greater theologian than St Thomas of Aquinam, a greater reformer than Luther, a greater orator than St Gregory the Great, though both are entirely forgettable. He wielded a mightier influence not only than all of these put together, but even than his fellow apostles St Peter and St John. The secrets of his unparalleled success were—regarded on their human side—the secrets of all success in the field of religious effort—hard labour, burning zeal, absolute self-sacrifice, undaunted courage, and a strong conviction that he was fulfilling a ministry to which he had received a special call from God.

Our chief and all but exclusive authorities for his life are the Acts of the Apostles and his own Epistles. The circumstances added by Christian tradition are highly dubious, and the voluminous inventions of Talmudic malice and Ebionite heresy may be dismissed with silent contempt. Paley in his Horae Paulineae has shown with wonderful skill and originality how remarkably the credibility of St Luke's history is supported by authentic touches of autobiography, even in cases where there is a seeming and superficial discrepancy. He shows us that even the undesigned coincidences can be counted by scores. From combination of the two sources we are able to arrive at a true picture and delineate his character both in youth and in later life. The life of St Paul is a like a manuscript of which the beginning and end are irrecoverably lost. All that we really know of his life lies between the thirty years between 36 A.D. and 66 A.D., which form its central period. We can only form slight and uncertain conjectures respecting the period of his youth, and early manhood, and respecting all that befell him after St Luke drops the curtain upon his first Roman imprisonment with the words, 'teaching with all boldness unmolested.' But in this central period the records are quite fragmentary. They close in 2 Cor. 12, St Paul having been on the road for about 57 A.D., some ten years before his death. St Paul briefly alludes to the strange and severe diversity of his trials; and yet of those which he mentions
no less than eleven special trials are not so much as alluded to in the Acts. St Luke does not mean here, as some think, the special trials of his martyrdom; only one of the three flagellations with Roman rods; not one of the three shipwrecks, though he minutely describes a fourth. He makes no allusion to the ‘night and day in the deep,’ and only mentions two of what Clement of Rome lists, the blindness of the girdle of Sardonyx, and the falling into the hands of the Gentiles. Probably the most striking thing is that St Luke refers to any one of the perils of watercourses, perils of robbers, perils in the wilderness, perils among false brethren, hunger, thirst, fasting, cold, and nakedness, for which we can only find places in the travels of the apostle by revelation. But it appears, however, as if St Luke endeavoured to make the account of his long and toilsome journeys, in St Jerome, perhaps following a true but confused and anarchistic tradition, says that St Paul was born at Giscela in Gallilee, and taken by his parents to Tarsus of Cilicia in early infancy. The conjectural date of his birth is about 3 A.D. Tarsus was at that time ‘no mean city.’ It was beautifully situated on the river Cydnus, and was a centre not only of political power and commercial enterprise, but of learning and scholarship. He grew up in the midst of paganism, but was trained ‘a Hebrew of the Hebrews,’ in profound acquaintance with the Jewish Scriptures, and with some slight knowledge of classical literature. Being of the tribe of Benjamin, he received the national name of Saul. Tarsus was only an urbs libera, but in some unknown way St Paul was a Roman citizen, and it has been conjectured that his father may have been one of the Tarsians carried by Cassius to Rome, and may there have married the rhetorician. He was sent, probably as a boy, to relatives at Jerusalem, where in after days he seems to have had a married sister. He there became an illustrious and learned Pharisee of the famous school of the Rabban Gamaliel (q.v.), a grandson of the sweet and noble Hillel. At the feet of this eminent doctor he sat for many years, endeavouring to attain to the legal blearinesseness which was the ideal of Pharisaic virtue, but which could give little satisfaction to his deepest yearnings. It was hardly wonderful that he should have imbued the spirit of fanatical hatred against the followers of the law of Moses, and to which a Pharisee seemed to involve the overthrow of all his most cherished idols and formalities. If, as he seems to imply, he had a vote in the Sanhedrin (Acts, xxvi. 10), he must have been married; and in the account of the Conversion (Acts, vii. 58-60, xxvi. 20; 1 Cor. xv. 9; Gal. i. 13), it has been inferred that he was a widower, and remained a widower by choice (1 Cor. ix. 5). Gamaliel approved of the wise policy of toleration; but Saul, less wise herein than his teacher, was hurried by what he himself afterwards and remorsefully described as a spirit of frenzied rage (Acts, xxvi. 11) into the attitude of a most violent persecutor. He haled men and even women to prison, hunted them out for punishment through every synagogue, scourged them (Acts, xxiii. 4), voted for their execution, and did his best to make their death the more hideous and public. He was the martyr of St Stephen by stoning, and on this occasion the executioners laid their garments on the feet of Saul. Fanaticism enabled him to witness that horrible death, but he was haunted hithermore by the light of Saul’s martyrdom. The face (Acts, vi. 15), the light of which he had seen quenched in blood (Acts, vii. 58-60, xxvi. 20; 1 Cor. xv. 9; Gal. i. 13). When he had finished his bad work as an inquisitor at Jerusalem, and had, as he hoped, extinguished the odious sect of Nazarenes, he obtained letters of authorisation from the high-priest, and went as commissioner of the Sanhedrin to root them out from Damascus. On his journey he met the crisis of his fate. He was, as he regarded it, arrested—supposedly Christ himself from the ground; taken captive, led in triumph, branded as a slave with the stigma of the Lord Jesus, when the dazzling vision, which onshore the Syrian noon, wrapped him as in a blinding sheet of flame, and filled him with the spirit of a visionary, and showed him and heard his risen Lord. From that moment he was a changed man. He felt that the fire of God had melted the iron sinews, and the hammer of God had shattered the stony heart. What is certain is that from that time forth the proud man became utterly humble, the great leader of the Judæo-christian, the hearted evangelist. The hard and self-sufficient Rabbin, abandoning for ever his national arrogance, his rabbinic wisdom, his legal scrupulosity, became the excentric the suffering and despised preacher of an executed faith.

It is needless to follow in detail the further narrative of the Acts or the personal indications of the epistles. Healed by Ananias of his temporary blindness, he retired for about three years to Arabia, and then returning to Damascus began powerfully to work amongst the Jews; but the party of the (Act. xv.) heretofore toiled to destroy. Driven from Damascus by Jewish animosity, he contrived to escape down the city wall in a basket, and made his way to Jerusalem, where, as was natural, he was received with coldness and suspicion, until Barnabas generously intervened to remove the prejudices of the brethren. After a trance and vision in the temple, in which his future destiny was foreshadowed to him, he was driven to Tarsus by a plot to murder him, and there he stayed with his family, waiting and preparing for his work. Meanwhile the capital of Christianity was being gradually transferred from Jerusalem to Antioch, and Barnabas, realising the importance of the vast sphere of labour which was there opening before him, set out to seek Paul as his fellow-labourer. At Antioch he laboured for a year with ever-widening influence, and went to Jerusalem with Barnabas in the year 44 to carry contributions to the necessities mother-church. Soon after his return began the first stirring of the missionary spirit, and Barnabas and Saul were set apart by divine consecration to preach the gospel to the Gentiles. They went to Lystra, where, healing a cripple, they were at first taken for gods; but a revision of feeling against them was again caused by the Jews, and Paul was stoned and left for dead. It is probable that he carried with him to the grave the marks of the cruel martyrdom; but at Lystra he had the happiness of winning a young convert named Timothy, the beloved son and companion of many later trials and travels, even to the end of his life. From Lystra they fled secretly to Derbe, and thence to Iconium, the capital of Antioch, appointing in each place elders over the infant churches. Such was the first flight of the eagle, the first journey of Christian missionaries. It confirmed Paul in his destined work as the Apostle of the Gentiles. Shortly after their return to the Syrian Antioch the church began to be troubled by the Pharisaic
Paul, who wished to reduce Christianity to the level of a local faction by forcing on Gentile converts the crushing yoke of Jewish circumcision. It is difficult after the lapse of many centuries to estimate the religious and originality which it then required to pronounce obsolete and abrogated, and to characterise as 'weak and leggery elements,' what all Jews regarded as the infinitely sacred and eternally inspired institutions of that Mosaic ceremonial, which had covered religion with the sanctity of an irreproachable tradition and the oral law. But Paul took this part boldly and decisively from the first and at all costs—willingly facing the obloquy heaped upon him as a renegade and a seducer of the people—he carried out to the end the indignant battle which saved Christianity from being degraded into a narrow sect and made it the universal religion of spiritual freedom. It was necessary for Paul and Barnabas to visit Jerusalem to obtain from the first church synod the decision of this great question, and the victory gained in that synod, mainly by the genius of St Paul aided by the many convictions of St Peter, is the most momentous in the history of early Christianity. It was indeed only a partial victory in the form of a local decision; but it practically conceded the matter and enabled St Paul to enforce on reluctant Judasists the emancipation of their Gentile brethren from a host of worrying restrictions, which, if unabridged, would have been justly fatal to the spread of Christianity. 

How strained were the relations between the two divisions of the church we see from the fact that shortly afterwards at Antioch Paul had to rebuke even the chief of the apostles publicly for something like tergiversation, into which he had been led for a moment by fear of his Jewish co-religionists. This was never forgotten, and we see from the Pseudo-Clementine writings that perhaps a century later there were Judaizing heretics who because of it dared to indulge in malignant calumnies against St Paul.

It was shortly after this memorable scene that St Paul's missionary ardour led him to propose to Barnabas the visit of Jerusalem for that of Barnabas to take with him his cousin Mark, and Paul's disinclination to admit the companion of one who in his judgment had put his hand to the plough and looked back in the first journey, led to a sad disagreement between the two friends. The argument however was settled by the fact that later Paul desired the presence of Mark at Rome because he found him profitable for the ministry. Paul, with Silas as his companion, went through the Cilician Gates to Derbe and Lystra. At Lystra he circumcised and ordained Timothy, who continued to be his dearest companion for many years. Thence they went through Phrygia and Galatia, preaching and founding churches.

In Galatia Paul had a severe illness, in which he was cheered by the bright enthusiasm of his Galatian converts. Provided with light refreshment, they were led to Troas, and there St Paul was joined by St Luke, and saw the vision of the 'man of Macedonia,' which led to the momentous decision to carry the gospel into Europe. They sailed to Neapolis, and were received at Philippi by the gentlewomen Lydia. The church founded was the most blessed by St Paul of all his infant communities. The healing of the girl with 'a spirit of divination' led to an uproar, in which Paul and Silas were unjustly and illegally scourged and imprisoned. An earthquake in the night dissolved the jail prison and all the prison guards were honourably dismissed. They went to Thessalonica, and founded another church, where Paul, who was generally able to support himself by his trade of tent-maker, was aided by the generous Philippian. Another riot, stirred up by Jewish jealousy, caused Paul to leave the Philippian and St Paul was again driven by Jewish machinations, and made his way to Athens. He preached on the Areopagus amid the jeers of Stoics and Epicureans, but won some important converts, and proceeded to Corinth. There, with the aid of his fellow tent-makers, Aquila and Priscilla, he founded an important church; but another riot arose in which both Jews and Greeks were involved, which was treated with disdainful indifference by the procure Gallio, the brother of Seneca.

After a stay of some months at Corinth, he revisited Jerusalem (Acts 15:22,35) and went to Ephesus, where he made a full convert of the eloquent Apollos, and stayed for two years. The immense success of his preaching led to the riot of the silversmiths in the theatre. Compelled to fly, he made his way to Troas and retraced his steps through Macedonia as far as Ilium, and thence to Corinth. But the evangelist was大厦ed by a severe storm, and his importance group of epistles. He was greatly occupied also in raising a contribution for the perennial destitution of the mother-church at Jerusalem, which was taken thither by chosen delegates of the contributing churches. A sudden plot of the Jews to murder him compelled him to return through Macedonia. He spent the Passover with Luke at Philippi, sailed to Troas, where he raised Eutychus from death, and then among the isles of Greece to Miletus, where he had an affecting parting with the elders of the Ephesian Church. A voyage past Crete, Rhodes, and Patara brought him to Tyre, where he was warmly welcomed by the church, and parted from them in prayer on the seashore. At Cesarea he stayed in the house of Philip the Evangelist, and thence, in spite of the warnings of the prophet Agabus, went up to Jerusalem. There he met Silas and Barnabas, and he was received by James, the Lord's brother, and the elders, to whom he handed over the Gentile contributions, in accordance with the old instructions of the synod of Jerusalem, 'to be mindful of the poor.' Afraid that his presence would cause him, the Holy Spirit speaking through the Jewish fanatics, St James suggested to him that he should take a share in the expenses of a Nazarene vow. The suggestion turned out unfortunately. He was recognised in the Court of the Women, and charged with having taken Trophimus, a Gentile Ephesian, into the temple. He was rescued from the brutal fury of the mob by the chief captain Lysias, who, taking him for an impostor, was on the point of having him scourged, when he discovered that he was a Roman citizen. Under the protection of the Romans he was tried before the Sanhedrin, but thrown the assembly into a tumult by taking advantage of the rivalry between the Pharisees and Sadducees. Among these perils a vision assured him that he should yet preach the word in Rome. Discovering that forty Jews had sullied themselves under a curse to assassinate Paul, Lysias sent him to the care of Felix at Cæsarea. He was tried before Felix, and made a deep impression: but, as he had no money to bribe the avaricious governor, he was left two years in prison. He was then tried afresh by the fair and energetic Festus, who also gave him an opportunity of pleading his case before King Agrippa II. and Bernice. Weary, however, with the long and unjust detention, he had appealed to Cæsar, and
Festus sent him, in charge of the centurion Julius, to Rome. St Luke, who, with Aristarchus, was his companion, gives us a minute account of the voyage to Myra, and thence in an Alexandrian wheat-ship to Crete, where they lay windsbound at Fair Havens. Continuing the voyage in spite of Paul’s warning, the crew were caught in a cyclone called Euro-aquila, and the ship, in spite of under-girding and every other precaution, became a complete wreck. Amid the despair and misery of all on board, St Paul, comforted by a vision, assured them of their safety, and though the vessel finally became a total wreck at Ræs el Koura, in Malta, every soul was saved. At Malta he remained three months for another ship. He was held in great honour by the barbarous natives because he had shaken a viper off his hand unhurt, and healed the father of Publius, the Protos of Malta. The prisoners were taken to Italy on board the Cæsar and Publius, and landed at Puteoli, proceeding by land to Rome. Paul was met by Christian brethren at Appii Forum and the Three Taverns, and went along the Appian Road to the capital, where he was handed over to the observation of Afinius Burrus, the praetorian prefect. For two years he continued to minister at Rome, and whilst he was there the Emperor refused to accept his preaching, he did what he could to make the gospel known to the Gentiles, gaining converts even among the praetorian soldiers and the slaves of Cæsar’s household, and being without any hindrance, and free to continue his work in the supervision of the soldiers. From the pastoral epistles we securely infer that his trial ended in a complete acquittal. His next movements are uncertain, but we find traces of his probable visits to Colosse, Crete, and Nicopolis, and of his final arrest in the house of Cæsar at Rome. He seems to have been tried and imprisoned at Ephesus, and again sent to Rome. Meanwhile the Neronian persecution had broken out, and his second imprisonment, in which nearly all desert ed him, was far more perilous and miserable than the first. At his first trial—perhaps before Nero in person—he seems to have been remanded; but at a second trial we learn from unanimous Christian tradition that he was condemned to martyrdom, probably, as he was a Roman citizen, by decapitation. His ‘trophy,’ which has become an international object of veneration in Rome in the 21st century, but his death was so lonely and unrecorded that not even tradition has preserved a single trustworthy detail respecting it. All that we can see from his last writings is that he remained heroic, indomitable, cheerful, faithful to the end, never doubting, amid an apparent failure which the world might well have regarded as absolute, that the hundredfold harvest of eternity would spring up from the grain which he had sown, in tears. Yet it is unlikely that even he, on this side the grave, was at all able to estimate the far-reaching grandeur and many-sidedness of the work which it had been given him to do. He had set an example of life-long zeal and devotion in the willing endurance of numebrless perils and privations, such as has never been equaled, much less surpassed; and he had done this with a mind acutely sensitive to the blasts of hatred which came to him from every region of the Jewish and Gentile world, and with a body weakened by chronic disease. He had formulated the language and systematised the doctrine which he had bequeathed the gospel from dwindling into a Pharisaei Judaism, and had established for ever its freedom from the yoke of priestly and ceremonial bondage. He had carried the faith over a vast extent of Asia from Jerusalem to Antioch, to Iconium, and Corinth, to Rome, and perhaps even ‘to the farthest limit of the west.’ He had been the founder of many flourishing churches. He had written epistles of various orders, of which even the most casual is ‘weighty and powerful,’ and which constitute him one of the greatest moral and spiritual teachers whom the human race has ever seen.

It only remains to glance at these epistles. They are thirteen in number, and fall into four well-marked chronological and doctrinal groups. The first group (1, 2 Thess., written 52–53 A.D., during the second missionary journey) are mainly eschatological, and represent St Paul’s earliest stage of thought. The second group, written during the third missionary journey, may be called broadly Apologetical. The third group, written (written at Epiphesus in 57) (3) is mainly polemical and ecclesiastical. 2 Corinthians (written at Philippi in 58?) is the apostle’s Apologia pro Vitæ Sæu. Galatians and Romans (written at Corinth in 58) are mainly doctrinal and soteriological. The third group are the epistles written during St Paul’s first imprisonment at Rome. Philippians (62) is personal and ethical. Colossians and Ephesians (63) are Christological, Ephesians being especially the epistle of the ascension. Philemon is an exquisite personal epistle, the first written by Paul; and Titus (64) a sort of annex to the Epistle to the Colossians. The fourth group contains the pastoral epistles of St Paul’s closing years. 1 Timothy and Titus may have been written in Macedonia about 60, 2 Tim. about 61. About 62 they were written. They may also be classified according to their forms, as (1) Circular letters to the churches (Eph. and Rom.), which are rather treatises than letters; (2) Letters to special churches, or little groups of churches (1 and 2 Thess., 1 and 2 Cor., Phil., Col., and Gal.); (3) Letters to friends (Philemon, Titus, 1 and 2 Tim.).

The genuineness of some of these epistles has been fiercely contested. Four (1 and 2 Cor., Gal., and Romans) are absolute homologoumena, of which not even the school of Tübingen questioned the genuineness; but they regarded 1 and 2 Thess., Philippians, Ephesians, Colossians, and Philemon as antilegomena, of uncertain authenticity, and the three pastoral epistles as spurious. The Christian church has amply met the arguments of the chief defenders of the sceptics (183) on this point, and even Renan only rejects the pastoral epistles, and that mainly on historic and chronological grounds because with many others he holds that St Paul perished in the Neronian persecution in 64 A.D.

The mission of St Paul was fourfold. Had he done nothing more than set the world an example of saintly self-sacrifice, his work would have been sufficiently memorable to make him immortal; but besides this he was a missionary, a moralist, a reformer, and a theologian.

1) Of his missionary work we have spoken, and have shown that to him pre-eminently belongs the honour of having made known the gospel to the civilised world around the basin of the Mediterranean; so that before his death the Christians had grown from a little community of 120 Galileans in an upper room at Jerusalem into a number of flourishing Asiatic and European churches, and even in that early day Christ had His followers in the Praetorius camp at Rome, and in Caesar’s household.

2) As a moralist St Paul laid down, with incomparable clearness, the relations of ethics to the gospel, and the secret of the loftiest moral standard as rendered possible by the new life. No moralist before him had more distinctly illustrated the eternal principles taught by Christ, by showing the concreteness of duties of life. To take but one example—no moralist ever dealt with the duty of purity, so universally
the Faith of Man. Luther rediscovered this truth theoretically by reading the epistles to the Romans and Galatians, and Galatians and Ephesians Christologically—i.e. they were written from the viewpoint of Christ. His doctrine of salvation is set forth psychologically. It is built on the moral facts of the universality of sin, the insufficiency of man, the justification of the believer by union with Christ.

In the later epistles the statement of faith and doctrine is made embodiment of the ethical and religious central being of the universe, and we see God's eternal plans realised by the unity of redeemed humanity in Christ with the family of heaven in the heavens.
Round these central truths all the other views of St Paul are crystallised. The fierce disputes in which rival dogmatists—St Augustine and Pelagius, the Jesuits and Jansenists, the Calvinists and Armenians, and many others—have combated over his opinions arise from the futile attempt to systematise exorbitant inferences drawn from isolated phrases, to forge upon their aporetical pyramids of argument, to obscure the whole heaven of Christianity with smoke made to issue 'from the narrow aperture of single texts.' Such attempts must always fail. St Paul's letters were écrits de conscience. What they convey is often hard to understand. They were edifying; they were the outcome of the special conditions with which they immediately dealt. St Paul 'never recoils before a paradox; he never cares to remove an apparent contradiction; he knew that truths which apparently contravert others are often complementary truths; he leaves side by side the apparent antinomies which arise from the contact of finite reason with infinite truth. He was well aware that when reason steps beyond the limits of experience it comes into collision with mysteries not only insoluble, but apparently opposed. Yet, in the first place, because a 'mysterium' was not concerned to reconcile the opposite facts of predestination and free-will; of universal restoration and a twofold end of probation, of the necessity for human effort and yet its insufficiency; he knew that here no perplexity in the region of practical life. While he created the language of Christian theology, and often enshrines a whole world of thought in a single word, he lends no sanction to the theological controversialists who, with mutual blinding, are perpetually accusing each other of dechristianising; because they involve no perplexity in the region of practical life.

The literature bearing on St Paul is vast in extent; the following are merely the names of the more important modern books: (1) Life.—K. Schrader, Der Apostel Paulus (1830-36); Neander, Gesch. der Pflanzung u. Leitung der Christl. Kirche durch den Apostel Paulus (vol. I. 1882; Eng. trans. 1881); F. G. Baur, Paulus der Apostel Jesu Christi (1845); 2d ed. by Zeller, 1866; Eng. trans. 1878-79); A. Hausrath, Der Apostel Paulus (1863; 2d ed. 1872); Ch. F. Trüp, Paulus der Apostel (1870); R. W. F. Brem, Paulus der Apostel Jesu Christi (1866); and Saint Paul (1899); F. Bungener, S. Paul, sa Vie, son Éuvre, ses Édits (1867); M. Krenkel, Paulus, der Apostel der Bekenner (1890); W. J. Conybeare and R. Taylor, The Life and Epistles of St Paul (1852); F. W. Farrar, The Life and Work of St Paul (1879); Lewin, The Life and Epistles of St Paul (1851; new ed. 1874); and good shorter studies by O. H. Taylor (1884), J. Stalker (1884), and Professor Iverach (1891). (2) Theology.—Ritschl, Die Entstehung der altkatholischen Kirche (2d ed. 1857); A. Sabatier, L'Apôtre Paul (1879; 2d ed. 1881); K. Holsten, Zum Evangelium des Paulus u. Petrus (1888) and Das Evangelium des Paulus dargestellt (1889 and seq.); C. Schmidt, Die paulinische Christologie (1870); O. Pfeiffer, Der Paulinismus (1873; 2d ed. 1880; Eng. trans. 1884); T. Tholuck, Das Christentum nach den paul. Ansichten d. Apostel (1878); C. Neumann, Die paulinische Christologie (1881), H. Gunkel, Die Wirkungsgeschichte des Heil. Gründers (1888); and his shorter work, Der Generalwille an der Grundlage des New Testament by C. Schmidt (1888); and Ch. Rogge, Die Anschauung des Apostes Paulus von die relig.-theol. Char. der Heil. Schrift. (1888); and especially the commentaries on the New Testament by C. F. Schmid (edited by Weizsäcker, 1853), Hauré (1846), B. Weiss (1888; Eng. trans. 1888-89), and J. V. Oosterze (1888; 2d ed. 1890).

See also the relevant parts of the Introductions of Bleek, Weiss, S. Davidson, Salmon, Holtzmann, &c.; and especially the works devoted to the Acts by Overbeck, Haucke, Zeller, Zahn (1869; Eng. trans. 1875-76), W. Wendt (1888, in Meyer), and K. Schmidt (vol. I. 1882); also C. Weizsäcker, Das Apostol. Zeit.

The names of which will be found under the special articles therewith. Of these may here merely be mentioned, as masterpieces in their kind, those of Gudert on Romans and Corinthians and Lightfoot on Philippian, Galatians, Colossians, and Philemon.

Specially noteworthy articles on St Paul are those by Hausrath in Schenkel's Bibel-Lexicon; by a Schilling in Richen's Handwörterbuch des deut. Alterthums; by a Smith in the first edition of Herzog's Real-Enzyklopädie, W. Schmidt in the second edition; and Hatcher in the Encyclopedia Britannica (9th ed.). The so-called Tubingen theory of the Origin of the Pauline and Petrine parties in the early church is maintained in the books by Baur (q.v.), Holsten, Zeller, and scholten, already mentioned. See the article Christianity in the representative work.

Paul was the subject of five papers: Paul I. (357-769) and Paul II. (446-71) were unimportant. Paul III., Alessandro Farnese, reigned from 1534 to 1549, during a very critical period for the papacy. He was born at Carino in Tuscany in 1468, and was created cardinal-deacon in 1493 by Alexander VI., who had illicit relations with his sister. He showed great political ability, and was the champion of reform. The more moderate adherents of Pietro Luigi were at length frustrated. Yet in other respects he was a wise pontiff, and he had the prudence to surround his throne with good cardinals like Contarini, Pole, and Sadolet. He convoked a general council to meet at Mantua in 1532 but it did not legally assemble (in Trent) until 1545. The ball of excommunication and deposition which he issued in 1538 against Henry VIII. of England is a late example of the exercise of the temporal power claimed by the medicean popes. The bull instituting the order of the Jesuits (1540) is important as marking the beginning of the Roman counter-reformation. In the contest of Charles V. with the Protestant League in Germany Paul sent a large force to support the emperor, and he opposed the pacification proposed by the Interim. And in the struggle between the emperor and Francis I. he tried to trim in order to save the peace of Italy and the interests of his bastards. He died suddenly, November 10, 1549.

Paul IV., named Giovanni Pietro Carafa, a member of the family of that name, was born in Naples in 1476. His early career was distinguished for ascetic rigour. He was appointed Bishop of Chieti, in which see he laboured most earnestly for the reformation of abuses, and for the revival of religion and morality. With this view he established, in conjunction with some congenial reformers, the congregation of secular clergy called Theatines, and was himself the first superior. He showed himself the most rigorous enemy of heresy, and it was under his influence that Paul III. organised the tribunal of the Inquisition in Rome. On the death of Marcellus II. in 1555, although in his seventy-ninth year, he was elected to succeed. He enforced vigorously upon the clergy the observance of all the clerical duties, and enacted laws for the maintenance of public morality. He took a censorious view of the friars, and finally to a full official Index librorum prohibitorum, and completed the organisation of the Roman Inquisition; he took measures for the alleviation of the burdens of the poorer classes, and for the better administration of justice, and even by issuing a bull he banished from Rome on account of their corrupt conduct and profligate life. His foreign relations, too, involved him in much labour and perplexity.
He was embroiled with the Emperor Ferdinand, with Philip II. of Spain, with Cosimo, grand-duke of Tuscany, and many others, in which the weight of his strength gave way, and he died, August 18, 1599. His severity had been hateful to the Roman citizens, who hailed the news of his death with delight.

Paul V., originally named Camillo Borghese, was born at Rome in 1532. In his early life he was a distinguished canonist and theologian; and, after the ordinary prelatical career at Rome, he rose first to the post of nuncio at the Spanish court, and afterwards to the cardinalate under Clement VIII. On the death of Leo XI. in 1605 Cardinal Borghese was elected to succeed him. His pontificate is rendered memorable by the celebrated conflict with the republic of Venice, into which he was plunged at the very outset of his reign. The original ground of dispute was the question of the immunity from the jurisdiction of civil tribunals conceded to the clergy, who claimed to be tried by ecclesiastical tribunals alone. This claim the senate resisted; and further causes of dispute were added by a mortmain law, and a law prohibiting the establishment of new religious orders or associations, unless with the sanction of the senate. Eventually, remaining inflexible in its determination, Paul issued a brief, directing a sentence of excommunication against the doge and senate, and placing the republic under an interdict, unless submission should be made within twenty-four days. The senate persisted, and an animated conflict, as well as acts of writings, ensued, in the latter of which the celebrated Fr. Paolo Sarpi, on the side of the republic, and on the papal side Bellarmine and Baronius were the leaders. By the intervention of Henry IV. of France the dispute was accommodated in 1607, but not until then had pope had compelled to abandon his claims. Paul's administration was vigorous on behalf of orthodoxy, and he did a great deal for the promotion of useful public works, for the embellishment of the city, the restoration and preservation of antiquities, the improvement of the museums and libraries, and, above all, for the pious and charitable institutions of Rome. Paul died January 28, 1621, and was succeeded by Gregory XV. See T. A. Trollope's Paul the Pope, and Paul the Friar (1860).

Paul, emperor of Russia, the second son of the unfortunate Peter III. and the Empress Catharine the Great, was born October 17, 1771, became heir-apparent on the death of his elder brother in 1780, and succeeded his mother on the imperial throne in 1796. The tragic death of his father when he was still a child, and his mother's neglect, exerted a baneful influence on the character of Paul, who was kept in seclusion while Catharine and her favourites governed. His earliest measures were the exile of his father's murderers, and the pardon of Polish prisoners, including Kosewusko. But he soon revealed his capricious and violent temper, as well as his lack of capacity, and irritated all classes of his subjects by revocatory and imperious regulations. Not less unhappy and variable was his foreign policy. After beginning with an attitude of neutrality in the war between France and the rest of Europe, he suddenly declared in favor of France, and then, as was usual with him, made a levy of 50,000 men under Suvorov in Italy. Encouraged by his success, he despatched a second army of equal strength to co-operate with the Austrians, but its defeat in 1799 induced him to recall Suvorov; whereupon he retired from the allied coalition with Russia, engaged with Fries and Wellington, and entered into a close alliance with the First Consul Bonaparte. Paul now concluded a convention with Sweden and Denmark for the purpose of opposing the rising interest on behalf of the English of searching neutral vessels, with the result that the English government sent a fleet to intercept the Baltic convoys, under Scawen. He died, August 12, 1801, at St Petersburg. Among the conspirators were Count Pahlen, General Bennigsen, and other distinguished officers. The only aim was to delay and to open Paul to abduction; but a seuttlo arose in which the emperor was strangled, March 24, 1801.

Paul, CANONs of ST. See Barnabites.

Paul of Samosata, the Socinus of the 3d century, was born at Samosata on the Euphrates, capital of a district of Syria, and in 260 became bishop or patriarch of Antioch, the most important see of the East. Antioch then belonged to the Palmyrene kingdom, and Paul was practically the viceroy of Queen Zenobia, from whom he received support in the maintenance of his heresy. This was monoarchianism—the doctrine that Father, Son, and Holy Ghost are the one God, and that the Father has from all eternity produced the Logos, who is his Son, but is rather an attribute than a person. Antioch being reoccupied by Aurelian in 272, Paul's enemies procured his deposition by the heathen emperor; but his doctrines survived, and he had followers, Paulinists or Samosatensians, till the 4th century.

Paul, VINCENT DE. See Vincent de Paul.

Paula. See Francesco di Paula.

Paulding, James Kirke, an American author, was born in Dutchess county, New York, August 22, 1779. Self-educated, he early showed a tendency to literature, and, being a friend of Washington Irving, wrote a portion of Salmagundi. During the war of 1812 he published the Diverting History of John昨, and in 1814 published more serious work, The Dutchman's Fireside, and in 1832 Westward Ho! which attained to a similar popularity. These were followed by a popularly written Life of Washington (1835), and Slavery in the United States (1836), in which the institution was condemned on social, economical, and political grounds. In 1837 Van Buren appointed him Secretary of the Navy. Four years later he retired to a country residence at Hyde Park, New York state, where he died April 6, 1860. The well-known patrix lines, 'Peter Piper picked a peck of pickled peppers,' &c., occur in his satirical novel Rouncingame (1823). Four vols. of his Select Works were edited by his son (New York, 1867-68).

Pauli, REINHOLD, a no less learned than genial historian of England, was born in Berlin, 25th May 1823, studied at Bonn, next paid a long visit for purposes of study to Cambridge and to Oxford and Cambridge, 1848 at Oxford, and acted from 1849 till 1852 as private secretary to Bunsen. In 1855 he returned to Germany and habilitated at Bonn, whence he was called to a chair at Rostock in 1857. He obeyed a call to Tübingen in 1859, but during the 1860-61 war he was compelled to resign, and he received the little seminar at Schulpin for an article on the policy of Württemberg in the Preussische Jahrbücher. But he soon left this place, and was appointed to a chair at Marburg in 1867, at Göttingen in 1870. He died at Bremen, 3d June 1882. Pauli's chief work is English History, which has a place in the English history, and the value of his work had long been known to students before it was recognised by the D.C.L. degree conferred by Oxford in 1874. His excellent book on Alfred (1851; Eng. trans. 1852)
induced Lappenberg to commit to him the task of continuing the Geschichte von England in the great series of Heeren and Uckert. Paul's part (vols. 3–5, Gotha, 1833–38) begins with Henry II., and comes under the reign of Henry VIII., while portions of its ground have been more fully treated since, remains still the best history of mediæval England. Other works are Bilder aus Alt-England (1860; Eng. trans. 1861), Geschichte Englands seit den Friedensschlüssen von 1814 und 1815 (1864–67), and Nurembergs Martyrer der Religion (1867, Eng. trans. 1876), Aufsätze zur englischen Geschichte (1869; new series, 1883), besides an admirable edition of Gower's Confessio Amantis (3 vols. 1856).

Paulicians, a heretical Eastern sect, who owe their name to their peculiar reverence for the apostle Paul and his writings; but they called themselves 'Christians' only. Their founder was Constantine of Manazalis, near Samosata, who founded his first congregation at Cibossa in Armenia about 660. He was put to death by the emperor's order in 687, his successor, Titus, in 690; whereupon the adherents of the sect fled to Episparis under the Armenian Paul as leader. Later heads were Sergius, who carried on the persecution, and Flavia, who led an Armenian to Aragcaen in Saracen Armenia; Karbas, who built the cities of Amara and Tephриca for the remnant saved from the Empress Theodora's merciless severity, and Chrysoschores, on whose defeat by an army of the Emperor Basil they were utterly exterminated. Some of the converts were transferred by the Emperor John Tzimiscus to Philippiopolis in Thrace; a century later great efforts were made for the conversion of these, and the new city of Alexiopolis was built opposite for the converts. The sect, called Paulicians by Vilhelmond, continued to exist in Thrace into the 13th century. And it has been affirmed that remnants survived at Philippiopolis and in Bulgaria into the 19th century. The Cathari (q.v.) and Bogomilii (q.v.) were similar or related sects.

Many ancient Scriptures which they accepted were the four Gospels, fourteen Epistles of Paul, the three Epistles of John, James, Jude, and an Epistle to the Laodiceans. They rejected the title of Theotokos, refusing all worship to the Virgin, as well as any reverence to the symbol of the cross, and many of them refused the Holy Eucharist and the Holy Supper and baptism. Photinus, Petrus Siculo, and others identified them erroneously as a branch of the Manicheans; and the statement heretofore accepted that they maintained, like the Manicheans, a dualistic system (the Evil Spirit being the ruler of the visible universe) is denied by Conybeare, who affirms them to have been simply Unitarians, holding Christ to have been one with the Holy Ghost, and a creature. Gieseler and Neander connected them with the Gnostic Marcionites.

See the Church Histories of Gieseler and Neander; F. Schmidt, Hist. Pasch. Orientalium (Copen. 1836); Lombard, Pauliciensis, Bulgares et Bona-hommes (Geneva, 1879); Ter-Mersechian, Die Paulicien (Leip. 1883); and F. Conybear's translation of The Key of Truth, the Manual of the Paulician Church of Armenia (1888).

Paulinus, missionary to Northumbria, counted as the first of the archbishops of York. He was a native of Rome, and may have been named Run before his conversion. He was sent on his mission by Gregory in 601, and firstlaboured under Augustine in the evangelisation of the new kingdom. He came over with Augustine and was consecrated bishop in 625, when he accompanied Ethelburga on her marriage to the still heathen Edwin, king of Northumbria. For a long time he made no progress in his mission beyond baptising the infant princes; but at length a great gathering was held at Goodmanham, near York, to consider the matter, and in consequence Edwin and his court submitted to baptism at York, in a wooden chapel dedicated to St Peter, the foundation of the Minster, Easter Sunday 627. Paulinus now carried the gospel over the remainder of the country. His constant labour the death of Edwin in battle at Hatfield put a sudden end to his work. He did not wait for the honour of martyrdom, but went back with the widowed queen to Kent. In the same year he received the pallium as Archbishop of York from Rome, but he never returned, dying on October 10, 644. He was buried in the chapter-house at Rochester. See Dr Bright's Chapters of Early English History, and vol. i. of the Lives of the Archbishops of York.

Paulinia. See GUAARANA.

Paulovnia, a genus of trees belonging to the Scrophulariaceæ, with but one species, P. imperialis, a native of Japan, and now grown in the United States. It has heart-shaped leaves, and large panicles of purplish flowers. The name is derived from that of a Russian princess Paulovna.

Paul's, St. For the Cathedral, see LONDON; and for the school, see ST PAUL'S SCHOOL.

Paulus Emilius. See EMILIANUS, PAULUS.

Paulus, Heinrich Eberhard Gottlob, one of the pioneers of German rationalism, was born at Leonberg, near Stuttgart, 1st September 1761. His father's scepticism about the resurrection was cured effectually by a promised appearance of his wife after death. His own unphilosophic belief was succoured by an eager belief in spiritual visions which brought about his deposition from the office of Diakonos. The son studied at the Tübingen seminary, travelled in England, Holland, and France, and was called to the chair of Oriental Languages at Jena, which he exchanged in 1793 for that of Theology. Here he produced his laborious yet little read Philologisch-kritischer und historischer Commentar über das Neue Testament (4 vols. 1800–4); Cleis über die Paulinen (1791); Cleis über die Jesuus (1793). In 1813 he accepted the chair of Theology at Würzburg, next filled scholastic offices at Bamberg, Nuremberg, and Ansbach, and again in 1811 accepted a chair as professor of Church History at Heidelberg. Here he died, August 10, 1817, in the midst of his preparations for the publication of his Leben Jesu, as Grundlage einer reinen Geschichte des Urchristenthums (2 vols. 1828), and Exegetisches Handbuch über die drei ersten Evangeli (3 vols. 1830–33). His chief critical principle is an assertion of the impossibility of the supernatural, and the miracles of Christ he therefore explained as due to a variety of mistaken opinions and errors in narration—a series of exegetical miracles postulated to get rid of the historical. Paulus lived long enough to see his own rationalistic theory of Scripture give place to the more scientific mystical theory of Strauss, and that in its turn shaken to its foundations on the one hand by the Tübingen school, on the other by Neander and his school.

See Paulus' Skizien aus meiner Bildungs- und Leben geschichte zum Andenken an mein 70-jahriges Jubiläum (Augsburg 1839), and Reichlin-Meldeg's Paulus u. s. Zeit (1853).

Paulus Egineta, a celebrated Greek physician, was born in the island of Ægina, and flourished most probably during the conquests of the calif Omar in the 7th century. Of his life it is said that he pursued his medical studies first at Alexandria, and afterwards in Greece, and other countries. He had much knowledge and skill in surgery and obstetrics, and his Synopsis of the Medical Art has gone through many editions both in its original Greek and in Latin, English, and other translations.
Paulus Diaconus, the greatest of the Lombard historians, was born at Friuli about 720. He instructed Adelpurga, daughter of King Desiderius, and most probably resided at the court of her husband, Arichis, Duke of Beneventum. He became a Benedictine monk at Monte Cassino, about 774, but seems later to have spent some years at the court of Charles. He died before the coronation of Charles as emperor, therefore not later than 800. Of his works the earliest is the Historia Romana, an epitome of events based on Epitropius, with additions compiled from Eutropius, Firmicus, and Jordanes. This work was extended with interpolations by Landolf the Wise (c. 1000), and the whole compilation has been known as the Historia Mixtula; there are editions by Eynsenhahr (1889) and Droysen in Mon. Germ. Hist., 4. Aufl. 2. The Historia Langobardorum comes down to the death of King Liptrand (744), and is largely compiled from Gregory of Tours, the Origo Gentis Langobardorum, the short history (De Gestis Langobardorum) by Abbat Scernimus of Trent (died 612), and other sources. His work is an epitome of Gregory's own writings and from Bede: Gesta Episcoporum Metteusium, written at the request of Bishop Angelram, containing an interesting account of the rise of the Carolingian house, the founder of which was Arnulf, Bishop of Metz. in 715. It is written in an Epistolary form, in the style of the De Significatione Verborum of Sextus Pompeius Festus (ed. by K. O. Müller); a Book of Homilies, consisting of 298 sermons selected from Ambrose, Augustine, Chrysostom, Gregory, Jerome, and Leo. Poems, in honor of St. Benedict, in praise of the Lake of Como, &c. (ed. by Dümmler in the Monumenta Germ. Historia, Poetarum Latinorum Medii Âevi, i.); and Letters, to Adelpurga, Adelhard, Charles, and others.

Paumota. See Low Archipelago.

Pausanias, a famous Spartan regent and general, the son of Cleombrotus, and nephew of Leonidas, commanded the Spartan forces in the important battle of Platea (479 B.C.), in which the Persians were totally routed, and their leader, Mardonius, slain. He then marched his troops against Thebes, and compelled the inhabitants to give up the chiefs of the Persian party to him for punishment. For this feat, however, he became in an extreme degree haughty and vainglorious, took all the credit to himself, and allowed none to the Athenian generals, Aristides and Cinna, who commanded under him, and treated all the other Greeks as if the Spartans were their lords. Nevertheless, he still continued his conquests, capturing Cyprus and Byzantium. It was here he first began to play false to Greece. He entered into secret negotiations with Xerxes, with the view of becoming ruler, under the Persian monarch, of the whole country, and, in his journey through Thrace, even adopted the dress and luxurious habits of a Persian satrap, and surrounded himself with a bodyguard of Persians and Egyptians. He was recalled, on account of these things, by the Spartans, but his former services procured his acquittal. He then resuming his power, to which he renewed his traitorous intrigues, was expelled from the city for a criminal assault upon a Byzantine lady, withdrew to the Troad, and there continued his treachery. He was a second time called to account by the Spartan ephors, but again escaped, though with great difficulty. Yet his supremacy of Greece, even though at the expense of the national liberties, once more drove him to play the traitor. He tried to stir up the Helots, but was taken in his own net. A Helot betrayed him. When Pausanias found his position desperate he took sanctuary in a temple of Athena. Hereupon the people forced up the gate of the temple with heaps of stones, and left him to die of hunger, his own mother depositing the first stone.

Pausanias, one of the most eminent of Greek geographers and historians, was probably a native of Lydia in Asia Minor, and flourished under Hadrian, Antoninus Pius, and Aurelius. He traveled through all parts of Asia Minor and Europe, and through part of Asia and Africa, and composed from his observations and researches an Itinerary of Greece (Hellas Periégéseis) in ten books, describing the different parts of that country, and giving a particular account of the monuments of art and of the legends connected with them. His style is unpretentious and easy, although devoid of any special literary grace, but his itinerary possesses the rare merit of being the work of an honest and accurate eye-witness. Pausanias was a man of marvellous industry, and is one of the most important and most useful of the full modern sense of that word. Even in his treatment of works of art he is ever the antiquary rather than the critic, and his observations seldom rise out of the prosaic atmosphere proper to the catalogue. But he has the saving grace of accuracy, in his history and in his itinerary. Pausanias is one of the most precious records of antiquity that we possess. He has not grasped the distinction between legend and history; or, more correctly, dominated by the instinct of the collector, he has recorded everything that he learned, historical fact and legend alike; and hence his work is a mine of wealth to the student of mythology and folklore, no less than to the archeologist proper.

The best editions are those of Siebels (5 vols. 1822-31) and of Schubart and Walz (3 vols. 1838-40)—the latter reprinted in Teubner's series (2 vols. 1892). There are English translations by A. R. Shilleto and J. G. Frazer. See also Kalkmann, Pausanias der Perser (1886); and Margaret Verrall's Mythology and Monuments of Ancient Athens (1890).

Pavement. flat stones or 'flags,' seldom exceeding five inches in thickness, used for covering footpaths, courtyards, kitchens, &c. (see flagstones). The name is also given to the stone covering of the carriage-way of streets. The Romans paved both their streets and their highways with stones in a most substantial manner, but under Charles the Great this art was almost all unmade. At Pompeii the stone pavement of the narrow streets remains in the same state as it was before the city was destroyed, and shows the ruts made by the bire or carriages. It is formed of polygonal blocks of stone, like cyclopean masonry, the largest pieces being about 3 feet across the face. This kind of ancient Roman pavement, the remains of which are found at other places in Italy, is laid on a carefully prepared basis or foundation, sometimes composed of several layers of suitable materials. Modern pavements in Europe and elsewhere are still mostly largely paved with hard stones of various kinds, roughly dressed into oblong blocks, say 12 in. by 4 in. and 6 in. deep, and smaller sizes. These are generally laid on a foundation of sand or very fine gravel, sand being also used for filling the joints. But this way of laying a pavement is done with pitch. Granite and some varieties of Basalt (q.v.) are extensively quarried for these paving-stones.

Wooden pavement consists of pieces of wood (in northern Europe usually that of Pinus sylvestris) about the size of paving-stones, laid and nailed on boards, with asphalt or concrete below them, and
with the joints of the wood blocks pitched. Vehicles make least noise on this kind of pavem-
ment. The expense of letting is less, and the cost of keeping it in order under heavy traffic, continues in favour. Asphalt pavement is also a good deal used both for foot and carriage ways. It is described under Asphalt. Both this and wood pavement are apt to be slippery in wet, and the latter in frosty, weather.

For foot-pavement and Portland cement concrete has been much employed of late years. Small stones, such as granite, crushed into small chips like beans, or not much larger, are mixed with the cement, which is laid on a bed of broken whin-
stone or 'road-metal'. Pavement so made is cheaper than the lime stones are used, but lower experience of it is necessary before we can say that it is in the long run more economical. The frequent necessity for lifting pavement when laying down or repairing gas or water pipes is a great drawback to the keeping of it in good order.

**Pavia.** a city called Ticinum in Italy, on the left bank of the Ticino, 2 miles above its confluence with the Po, and 21 miles by rail S. of Milan. A covered brick bridge (1353) connects the city with the suburb of Ticino, on the right bank of the river. Pavia is still in great part surrounded by walls; in 1867 the town was remodeled, and in former times it was called the 'city of a hundred towers.' Its oldest church is the Lombard basilica of San Michele, which, although the date of its foundation is uncertain, is mentioned as early as 601. The early 'kings of Italy' were crowned within its walls; in 1835 it was granted the title of 'royal basilica,' and was restored 1863-76. The cathedral, containing some good paintings, was commenced in 1488, but was never finished. It shelters the tomb of Boëtius (brought from St. Peter's) and relics of S. Ambrose, who was a native of Pavia; to it are the ashes of S. Augustine, in a Gothic sarcophagus ornamented with a great number of bas-reliefs and figures. The Certosa, which lies 5 miles north of the city, is described in a separate article. The castle of the Visconti (begun in 1300), a massive square towered structure, once contained valuable collections of MSS., armour, and curiosities, but they were carried away by the French in 1850.

The university is said to have been founded by Charlemagne, and was a famous seat of learning during the middle ages; but it was not formally constituted a university until 1361. It is now attended by 1000 students (1800 about 1850), who are taught by sixty teachers. Attached to it are two colleges—Borromeo (1563) and Ghislieri (1560) —for poor students, and a library (1772) of 150,000 vols., anatomical and natural history museums, a botanic garden, a school of the fine arts, &c. There is neither much industry nor much trade. Pop. (1861) 29,836; (1891) 32,339.

Pavia, the ancient Ticinum (afterwards Pavia, whence the modern name), was founded by Gallic tribes, and was sacked by Attila (452) and by Odoacer (476); Theodoric selected it as his capital after 498. Later on the Lombards made it their capital, and then it became the chief city of the kingdom of Italy. Through jealousy of Milan it shed with the emperors (1055-1056); it was then ceded by an imperial edict. Later it was altered by the French. It was stormed and pillaged by Napoleon in 1796, and came into the possession of Austria by the peace of 1814. Since 1859 it has been included within the kingdom of Italy. Lanfranc and Pope John XIV. were natives.—The province of Pavia (1312 sq. m.) has a pop. of (1889) 513,983.

**Paving.** See Pavement.

**Pavlograd,** a town of South Russia, 45 miles by rail ENE. of Ekaterinoslav, on an affluent of the Dnieper, was founded in 1780 by Zaporogian Cossacks. Pop. 14,442.

**Pavonida.** See Peacock.

**Pawnbroking.** Pawn is a contract whereby the owner of a thing delivers it to a creditor as secur-
ity for a debt or advance made by the latter to a third
party. This contract is of great antiquity, as may be seen on referring to the story of Judah and Tamar (Gen. xxxviii.) and the provisions of the Mosaic law (Exod. xxii.). In modern times the superior class of money-lenders have often advanced money on pledges of plate, &c.; this was the practice. On the Lombard streets, from whom Lombard Street in London takes its name; and it is said that the three golden balls which figure over every pawnshop were taken from the armorial bearings of the Medici family. Property of considerable value is sometimes pawned with bankers and others; and an equitable Mortgage (q.v.) may be described as a kind of pawn. Among the poorer classes, clothes, tools, &c. are frequently pledged when money runs short; like other small mortgaged articles they are called pawn, customers as an extortiour, though the profits of the trade are not particularly high. On the Continent efforts have been made to supersede the pawnshop by establishing what are called Monts de Piété. In England a quasi-charitable institution of the same kind was started in 1708, but it came to a disastrous end in 1731; another scheme, started during the bubble mania of 1824—
25, was equally unfortunate. In Ireland there were, in 1841, as many as eight Monts de Piété, but they had all disappeared in 1858. The bearing the name and charges of the Mont de Piété (q.v.) at Paris (the largest establishment of the kind in the world) with those of English pawnbrokers, it does not appear that there is any striking superi-
ority in the French system. It is understood that the Paris establishment is superior to the London pawnshop in two points—it charges a lower rate of interest, and it gives greater facilities for recovering stolen goods. On the other hand, it is said that officialism, which must prevail where a large staff is employed, makes it more difficult for the poor to obtain money. The rules of English common law which apply to a contract of pawn are founded in part upon the Roman law. The pawnbroker acquires what is sometimes called a special property in the goods deposited; he has a right to retain them, and, if the debt be not paid within the stipulated time, he has a right to sell; if the sale produces more than the amount of the debt, he must account for the surplus. The pawnbroker has a right to redeem at any time before sale; interest is not due unless the debt has run beyond the term provided for. These rules are considerably modified by the Pawn-
brokers Act, 1872, which applies to all persons who make a business of taking chattels in pawn, including the keeping of what in England are called dolly-shops, and what in Scotland used to be called 'famous persons.' Every pawnbroker is required to take out a license; unless in business before 1872 he must obtain a certificate of fitness from a magistrate or a petty sessions court before taking out a license. Pawnbrokers are required to keep books, with full accounts of their dealings, and are made liable to be searched under a magistrate's warrant. A ticket must be given on receiving goods in pawn; the pawnbroker may charge one halfpenny per month on each 2s. advanced; and there is also a small charge for the ticket. These charges are high, or rather would be high if the
PAWNERS

PAWNEES, a tribe of American Indians (q.v.), who formerly resided in Nebraska, with branches extending into Kansas and Texas. They surrendered their lands south of the Platte by treaty in 1833; suffered much thereafter at the hands of their hereditary enemies, the Sioux; and in 1876 removed, only 200 strong, to a reservation of 283,220 acres in Indian Territory. In 1887 they numbered only 918. See Grinnell's Pawnee Hero Stories and Folk-tales (New York, 1889).

PAWNEET, a city of Rhode Island, on the Pawtucket River, 4 miles by rail N. of Providence. A fall of nearly 50 feet on the river, and its proximity to the sea, caused it to be selected by Samuel Slater, in 1790, as the site of the first cotton-factory in the United States. It now contains numerous large mills, where cotton, woolens, haircloth, and thread are manufactured, besides great valuation of works for spinning and dyeing establishments, &c. Pawtucket was settled about 1653, and became a city in 1866. Pop. (1890) 19,030; (1895) 27,633; (1900) 39,224.

PAY

PAYMASTER, Sir Joseph, English architect and horticulturist, was born at Milton-Bryan, near Woburn, Bedfordshire, on 3d August 1803. He began life as a working-gardener in the service of the Duke of Devonshire, at Chiswick, and thence transferred to Chatsworth; there he was put in charge of the gardens, and entirely remodelled them, and was made manager of the duke's Derbyshire estates. The experience he obtained in designing garden conservatories at Chatsworth (q.v.) found wider scope in his proposal for a palace of glass and iron for the Great Exhibition (q.v.) of 1851. It was the first time these materials had been employed on so extensive a scale, and visitors found an inexhaustible theme of admiration in a fairy palace so novel, beautiful, and magnificent. His design obtained for him the honour of knighthood. He then designed the Crystal Palace at Sydenham (q.v.), and superintended its construction from the materials of the exhibition in Hyde Park. He also laid out the terraces, and planned the gardens, with their fountains, cascades, &c. Besides publishing many popular works, he edited the Botanical Magazine, Paxton's Flower-Garden, Pocket Botanical Dictionary, and other works. He died at Sydenham, 8th June 1865, having represented Coventry since 1854.

PAYMASTER-GENERAL, an officer of the British ministry, but not of the cabinet, who is charged with superintending the issue of all monies voted by parliament, but no control over the sums issued, paying merely on the order of the department concerned. He is always either a peer or a member of the House of Commons, and changes with the ministry. Sometimes the paymaster-general's post is unpaid, as in 1891. The paymaster-general is assisted by a treasury remembrancer, and deputy-paymaster for Ireland, and a staff of clerks.

PAYMasters, in the British army, are either 'regimental' or 'district.' There is one of the former, either a combatant officer or an officer of the army pay department, to every regiment of cavalry (except the Life and Horse Guards) and battalion of infantry. He receives drafts each month on the accountant-general for the various payments to which he has to make, and for the sums required by the captains, who then open accounts with some local bank, and draw upon them for cash to pay their men, &c. The amounts of the drafts are based upon monthly estimates, and all expenditure is accounted for in the 'pay-lists.' The paymaster's accounts are checked by the typewritten paymaster (an officer of the army pay department), and audited at the War Office, any wrong payments being disallowed. District paymasters also make all authorised payments to persons in their districts not dealt with by the regimental paymasters. On active service, and whenever local banks cannot be used, cash is carried in 'treasure chests,' which are in charge of the paymaster. The Paymaster-sergeant is clerk to the paymaster.

The naval paymaster is for a ship what the military paymaster is for a regiment; but in addition he has charge of the provisions, clothing, and miscellaneous stores, as well as of money. Paymasters (till 1844 called pursers) are commissioned officers, and rank, according to service, with lieutenants, commanders, and captains. The paymaster or accountant officer is responsible for all the naval accounts and victualling duties of the ship, and under the authority of the captain makes all disbursements for the naval service, the captain being held responsible that all accounts are sent in by the paymaster regularly, and that the balance of cash is correct. Candidates are nominated by the First Lord of the Admiralty, and, if they successfully pass a limited competitive examination, join as assistant-clerks. They must not be less than fifteen or over seventeen years of age. After one year's service, and being seventeen years old, on passing the necessary examination, they are rated clerks. After three years' service in this rank, and having passed an intermediate examination, and being twenty-one years of age, they can pass for promotion, and if successful they receive a commission as assistant-paymaster, ranking first with the junior lieutenants. The pay of an assistant-paymaster's seniority with junior lieutenants. From this time on their promotion, except in very rare cases, goes by seniority to paymaster, staff-paymaster, fleet-paymaster, who ranks with a commander, and paymaster-in-chief. This latter rank, however, is only given on promotion, and is not taken by paymasters unless the latter is 2s. 6d. a day, that of a clerk 4s., while an assistant-paymaster's range from 5s. to 11s. 6d. a day according to seniority, with an additional allowance
of 25. 6d. a day when in sole charge of a ship. The pay of paymasters, staff and fleet, &c. rises according to length of service from 14s. to a maximum of £1. 13s. per diem. All sailed a volley of poems, and the secretaries' clerks are now taken from the paymasters and assistant-paymasters.

Payn, James, a prolific novelist, was born at Cheltenham in 1830, and educated at Eton, Woolwich Academy, and Trinity College, Cambridge. In 1855 he was Eugenio Speroni, and the secretary to Leitch Ritchie as editor of Chamber's Journal, and in 1882 Leslie Stephen as editor of the Cornhill Magazine. Of his hundred novels may merely be named here Lost Sir Massingberd, A Woman's Vengeance, Carlyln's Year, Not Woung, the English Workman, The Talk of the Town, A Perfect Treasure, and The Heir of the Ages; The Disappearance of George Drifford and Another's Burden were published in 1897. Some critics preferred his shorter stories, essays, and criticisms to his novels, and thought his humour thin. There is much of interest in Some Private Vices (1882), Some Literary Recollections (1884), Gleanings of Memory, and Some Reflections (1894). He died 25th March 1898.

Payne, John Howard, born in New York City on 9th June 1792, had for thirty years a successful career as actor and author of plays, chiefly adaptations. The best known were Britons, Charles II., and Clari, which contains Payne's famous song, Home, Sweet Home. The music (to which perhaps its success was mainly due) is said to have been adapted from a Sicilian air by Sir Henry Bishop. Payne was appointed American consul at Tunis in 1841, and died there, 10th April 1852. It is a singular fact that the man who wrote Home, Sweet Home had never a home during the last forty years of his life, and that he died in the remains of the house, however, taken to America, and buried at Washington in 1883. See his Life and Poems, edited by G. Harrison (Albany, 1875; new ed. 1885), and C. H. Brainard's J. H. Payne (1885).

Payndú, the chief town of the Uruguayan department of that name (51'15 sq. m.; 28,417 inhabitants), is built on the hill granite-sloping from the Uruguay River, 290 miles by rail NW. of Montevideo. It is a busy port, and contains large slaughter-houses, and Timed meat, especially tongues, is exported. Pop. 13,000.

Paiz, La. See La Paz.

Pea (Pisum), a genus of plants of the natural order Leguminosae, sub-order Papilionaceae. Two species, supposed to be natives of the south of Europe and of the East, are very extensively cultivated for their seeds (peas), which are the best of all kinds of pulse—the Common Pea or Garden Pea (P. sativum) in gardens, and the Field Pea (P. arvense) in fields; both of them climing annually, with pinnate leaves, ovate leaflets, and branching tendrils in place of a terminal leaflet; the garden pea distinguished by having two or several flowers on each flower-stalk, the flowers either red or white, more generally white, and the seeds subglobular; the field pea having one flower on each flower-stalk, the flowers always red, and the seeds angular from crowding and compression in the pod. But it is not improbable that they are truly one species, of which the garden pea has, through the action of secret fathoms from the original type. Peas have been cultivated in the East from time immemorial, although the ancient Greeks and Romans do not seem to have been acquainted with this kind of pulse. Its cultivation was apparently introduced into Europe very early in the middle ages; and it now extends from warm climates, as India, even to very cold latitudes, the plant being of rapid growth and short life. The pea does not appear to have been cultivated in England even in the time of Elizabeth, and it was not until the end of the 18th century that it was brought from Holland, and were accounted 'fit dainties for ladies, they came so far and cost so dear.' The seeds of the garden pea are used for culinary purposes both in a green and in a ripe state, as are also the green succulent, pods of some varieties, known as Sugar Peas or Wyker Peas, in which the membrane lining the inside of the pod—parchment-like in most kinds—is much attenuated. Field peas are used both for feeding cattle and for human food. For the latter purpose peas are often prepared and deprived of their succulent which covers them, in a particular kind of vegetable which they are then sold as Split Peas, and are much in use for making Pea Soup. They are also ground into meal, which is used in various ways, chiefly for making a kind of pottage and unleavened bread. In the countries bordering on the Mediterranean, peas are roasted in order to eating.

There are innumerable varieties of the garden pea, but very few of the field pea, those of the former being so much the products of horticultural art that they cannot be preserved without the median character. Some of the field pea have long stems, and require for their support stakes 6 or 8 feet in height; others are of humbler growth; and certain dwarf kinds, preferred as most convenient in many gardens, succeed very well without stakes. They are usually sown in rows about 4 or 6 feet asunder. In Britain garden peas are sown at different times from January to the end of June in order to secure a supply of green peas during a considerable part of summer and autumn; and in the southern parts of the isles the peas are also sown in autumn and they are a little protection being sufficient for them during the winter. In the United States early peas are sown either in November or in February or March. Certain small kinds of very rapid growth, known as Early Peas, formerly preferred for the first sowings, although less productive than many others, are now being supplanted in the estimation of gardeners by larger and superior flavoured sorts, which combine the desirable quality of extreme earliness with the size and tenderness of the largest field, or so-called umberland or wrinkled varieties. Chalky and other calcareous soils are particularly suitable for peas, if to be used green, and in other soils a good field-crop is seldom obtained unless the land has been well limed, or manured with greenyard. The free use of lime is found to be unfavourable to the quality of field peas which are intended for human food, as peas from soil so treated do not readily melt or 'fall' in boiling, and are therefore more indigestible.

Market-gardeners in good districts in England find the pea a most profitable crop. Surrey, Bedfordshire, and Essex are the principal counties whence the supply for the enormous demand for green peas for Covent Garden Market is chiefly drawn. Supplies also are received from France in May, but are inferior in quality to the English. Peas are generally regarded to a considerable extent as a field-crop in Britain, but are best adapted to those districts in which the climate is least moist, the seeds being very apt to grow in the pods when moist weather prevails in autumn, by which the crop is thereby injured. As a rule the wrinkled kinds, being also in general the most bulky in straw, are very apt to lodge before the pods are filled in wet seasons, and particularly on rich land. The crop is, therefore, rather a precarious one.

The haulm or straw of peas is used for feeding cattle; and for its sake field peas are often reap before they are quite ripe, great care being taken
in stacking the straw to provide for ventilation, so that it may not heat. Pea haulm, when cut and dried green, is more nitrogenous and more nutritious than hay.

Land to be sown with field peas should be very clean, and in particular free of coulch-grass; otherwise the best management cannot prevent its becoming more foul whilst bearing the pea crop. The seed ought always to be sown in rows, not less than 18 inches apart. Various ears are employed for sowing peas; they are not unfrequently plunged under the furrow; but the seed ought not to be buried more than 4 inches under the surface. In the harvesting of peas the sheaves are generally left loose till the haulm is somewhat dry. In drying it shrinks very much. Winter Field Peas, a variety with very small seeds, are much cultivated in France and Germany, being sown in October, enduring the severest frosts without injury, and ripening very early.

Besides being one of its most important agricultural and horticultural crops, peas are largely imported into Britain, the quantity sometimes reaching 129,000 quarters. The chief sources are Denmark, Germany, Holland, Morocco, the United States, British North America; and of these Denmark supplies the greater part. As an article of food, if not taken too often or without other food, peas are very valuable, as they contain a large percentage of casein, which is a flesh-forming principle. This principle in the pea has been called legumin, but chemists are now generally agreed that it is identical with the casein of cheese. The chemical constituents of peas will be found in the table at Diets, Vol. III. p. 508; and the dietetic value is discussed at Food, Vol. IV. p. 719. Tinned peas are much used, but have little of the delightful flavor of this article.

A plant found on some parts of the shores of Britain, as well as of continental Europe and North America, and known as the Sea Pea, has been commonly referred to the genus Pisum, and called P. maritimum, although botanists now generally refer it to Lathyrus. It much resembles the common pea; has large reddish or purple flowers on many-flowered stalks; and its seeds have a disagreeable bitter taste. Its abundance on the sea-coast at Aldeburgh and Orford, in Suffolk, is said to have saved many persons from death by famine in the early days of this species of Lathyrus. Its common name is often given to species of other Papilionaceae genera. The Sweet Pea (q.v.) and Everlasting Pea are species of Lathyrus. The Chick Pea (q.v.) is a species of Cicer; and the Wool or Heath Pea is Orobus tuberosus.—The pods of peas are often injured by the Pea-beetle (Bruchus pisi), a small coleopterous insect; by the Pea-maggot, the caterpillar of a moth (Tortrix pisi); and by the Pea-weevils (Sitona crinita and S. lineata), small coleopterous insects.

**Peabody, a village and township of Massachusetts, 16 miles NNE. of Boston. Formerly called South Danvers, its name was changed in 1863 in honour of George Peabody, who was born here. The village contains the Peabody Institute, and the township has manufactories of carriages, leather, and glue. Pop. (1880) 9028; (1900) 11,523.**

**Peabody, George, American merchant and philanthropist, was born at South Danvers, Massachusetts, February 18, 1785. His parents, who were descended from the Paybolds of St Albans, Herfordshire, were poor, and his only education was a master's and the letters acquired of eleven he was placed with a grocer, and at fifteen in a haberdasher's shop in Newburyport. He was manager of a store in Georgetown for a time; in 1814 he became a partner in the dry-goods house of Elisha Riggs in Baltimore, and head-partner of his firm in 1827. He afterwards settled permanently. He established himself in London in 1837 as a merchant and money-broker, and accumulated a large fortune. He invested largely in United States bonds during the civil war; and this, coupled with integrity, industry, and splendid capacity in finance, was the secret of his marvellous success. As one of three commissioners appointed in 1848 by the state of Maryland to obtain the restoration of its credit, he refused all payment, and received a special vote of thanks from the legislature of that State. He was one of the chief organizers of the American department at the Great Exhibition. That same year he started his 4th of July dinners, which were of some account in fostering good feeling between England and America. During his lifetime Peabody gave away in all more than one and a half millions sterling for philanthropic purposes. Amongst his gifts were $10,000 to the second Grimnell expedition, under Dr Kane; $200,000 to the Peabody Institute, South Danvers (now Peabody); $55,000 to an institute in North Danvers; $100,000 to the University of Cambridge; and $25,000 to Phillips Andover Academy, and $25,000 to Kenyon College; $150,000 to found an institute of archaeology at Harvard, and a like sum for a department of physical science. His two largest gifts were $3,500,000 for the Southern Education Fund, and his contributions towards building industrial homes in London, which in all amounted to $250,000. Recognition of his benevolence was made by the United States government, while the Queen offered him a baronetcy or the Grand Cross of the Bath. He refused these honours, and was asked who had addressed a letter to the Queen of England which I may carry across the Atlantic and deposit as a memorial of one of her most faithful sons. The Queen's letter acknowledged his 'more than princely munificence,' to this she added her portrait, and both were deposited in the Peabody Institute, South Danvers. Peabody testified that his giving was really a triumph over a naturally parsimonious disposition; he lived and dressed plainly. The brave, honest, noble-hearted friend of mankind,' as the Hon. R. C. Winthrop called him, died in London, March 9, 1869. The net gain from rents and interest was £30,000. See Life by P. A. Forbes (1882). **

**Peace** is a term of important significance in law. International law regards peace as the normal relation of one state to another; this relation is disturbed by war, but when war is over the com- munities revert to their former rights, except in so far as they may have been changed.

In municipal law peace means the protection accorded to subjects of an established authority; thus, vassals were within the peace of their feudal lord. All subjects are within the peace of the sovereign, and judges and justices are appointed to keep the peace within their respective jurisdic-

wantonly invades the rights of another, is-
PEACE RIVER

The Peace River, a large river of Canada, rises in two branches in the Rocky Mountains, in British Columbia, and flows north-east to the outlet of Lake Athabasca, where it joins the Slave River by five widely separate mouths. The delta thus formed is, with that of the Athabasca River, the most fertile part of the country. The river has a length of about 1100 miles, but it is much enumbered with rapids. The Peace River was followed by Sir A. Mackenzie (1753-1820) in his expedition of 1792-93 (cf. his Voyages, 1801).

PEACH

The peach-tree, like the almond, is of moderate stature, more or less spreading, according to variety, deciduous (though some are called evergreen), and, when left to itself, deep-rooted. The leaves (which contain some prussic acid) are lanceolate, on short stalks, differ much in size, have their edges serrate or crenate, and have glands near the stalk or are glandless. The serrate leaves, as a rule, are glandless; the crenate have glands, and the glands are either eglobular or reniform. A d e r m a t h y know it to be the case, but as yet know not the cause of it, that mildew (both to the stone and fruit and leaf) attacks the varieties with glandless leaves, while the glandulose have immunity. And for this reason Royal George (one of the finest of peaches, but having boldly serrate leaves without any glands) is seldom planted now against the open wall where mildew has paid one visit. The many varieties of the peach pass into divisions and subdivisions, according to the point regarded. There is first the decisive difference in the clothing, flesh, and flavour of the fruit, which has established the broad distinction between peach and nectarine. A very close observer is the man who can pronounce in winter, unless the trees happen to be his own, which of twain is nectarine, and which is peach. In summer there is a certain difference, perceptible, but not easily described, in the tint and cast of foliage; while the fruit on the other hand leaves no doubt, even from its first appearance, as to its proper title. Tales have been told on good authority of the co-existence of the hard and the downy, the nectarine and peach, on the selfsame twig, and even of a fruit which was peach on one side of the suture and nectarine on the other. To deny what is outside one's own experience, however large that experience may be, proves it capable of increase; but to doubt the adverse instance is permissible. The present writer has grown hundreds of thousands of peaches, and some myriads of nectarines, but has never seen either become the other, though they often grow amicably on the same branch after budding. Peaches and nectarines, while distinguished as above, pass alike into the other three divisions which have been established concerning them—to wit: (a) those which have large and those which have small blossoms; (b) those which have glandless leaves and those whose leaves are glandular; (c) those that have fruit which adheres to the stone and those whose fruit parts freely. Neither of these points affects the other two, and hence arise cross-divisions. (a) As to size of bloom, it is hard to say why, but all known peaches and nectarines have blossom either very conspicuous or almost insignificant. Other fruit trees have blossom larger or middle-sized, or small, according to variety. Some gardeners fancy that the smaller bloom suffers les-
from the attacks of frost; the larger petals certainly show the nips more sadly, but the internal injury is received in either case. The colour of the blossom ranges from snowy-white to pink and rose (the latter being the most usual tint), and even to bright carmine.

(b) The leaves of the peach and nectarine, being as above described, furnish another classification according to the absence or presence of glands, and the form of glands when present. The gland is a small accretion or concretion upon the petiole, or at the base of the leaf itself; sometimes there is one gland at either edge, sometimes two, and at times even three. In form the glands vary from round to reniform; or even lentilial; but their function, if any, is not yet understood. Probably they take no active part, but are merely the tokens of a constitution adverse to fungoid outbursts. However that may be, they afford one more division of the peach and nectarine, according as they are glandless or glandulose, the latter subdivided into those which have round and those which are gifted with long glands.

(c) Again, the peach and nectarine are palpably divided (according to the inner construction of the fruit) into clingstones (or Paeves) and freestones.

Fig. 2.—Fruit of the clingstone (a) and freestone (b) varieties, cut across to show the seed.

In the former the stone seems to radiate, as it were by tentacles, into the flesh, and the eatable part will not quit hold without great loss of the delicious juice. These peaches are therefore only fit to be sucked, for to quarter them fairly is impossible. And it is a mark of indolence against the peaches of America that they belong mainly to the non-seecal section. But the freestones, chiefly grown in Europe, part from the stone with little rupture of tissue, and melt in the mouth instead of shewing on the plate. All the above being cross-divisions, the classes of the peach grow manifold; but the cultivation is the same with all. When grown on its own roots or on peach-stock the tree is short-lived, and being treated thus in America is worn out in some twenty-five years. In France it is worked upon the almond or the plum; in England the musset-stock is the most approved; and upon this it attains the greatest age. But grow it as we may, it is impatient of the knife, and must receive its orders at a very early date. In the southern parts of England both nectarines and peaches ripen well upon the open wall, or even on dwarf standards in fine summers, and fruit so ripened is the best of all; but the summers of recent years have much discouraged our faith in nature, which is now becoming confidence in glass.

Though many good varieties have been added lately by the skill of nurserymen, the older kinds are not yet obsolete; and the chief gain, if any, is in the lengthening of the period when ripe peaches of some sort can be gathered out of doors. American kinds, such as Alexander, Avenal's June, and Waterlow, may ripen on the open wall in July; but like other precocity are little worth. As yet we find nothing arisen newly to surpass our ancient friends Noblestone, Galtande, Grove Mig-

nome, and the like, well known for many generations, and chiefly of French origin.

[In the United States peaches are grown profitably as below described; but in the United Kingdom large quantities are sent to the markets, and the fruit, in some form, is brought easily within the reach of all classes. The principal peach-growing states are Delaware, Maryland, Virginia, Pennsylvania, and New Jersey, in this order; but the fruit is also largely cultivated in Georgia, Florida, and Texas for the early market, from near the great lakes down the Mississippi valley, and in California and Oregon. The canning of peaches is an important industry.]

For description of varieties, see André Leroy's Dis- 

ciclopedia.}

Peacock (Pavo), a genus allied to pheasants and other game-birds, including at least two species—the Indian and Singhalese P. cristatus, domesticated in Britain and other countries, and the Malayman P. muticus, inhabiting Java, Borneo, and similar regions. The Indian peafowls live in flocks, and are usually in mountainous and hilly districts, and are often accompanied by the tiger; though whether the tiger derives benefit from the wariness or flesh of the birds is uncertain. The birds roost in trees, and eat omnivorously—worms, insects, small snakes, seeds, &c. At the pairing season rival males display the well-known beauty of their tail-coverts before their desired mates, and strut about after the fashion of many game-birds. They sometimes fight fiercely with their rivals, and the females sometimes pay court to the males. Polygamy prevails, but there seems no truth in the old stories about the cruelty of the males to their mates. The usual cry is a shrill Pao, and strange noises are made by rattling the quills. The females lay, according to the climatic conditions, from April to October; the eggs, of a brownish colour, are numerous (eight to ten), and are laid without a nest in some concealed part of the jungle. At first both sexes are alike in plumage, but after a year or so the males gradually acquire their gorgeous feathers, which are perfected about the third year. It is not necessary to describe these colours, so delightfully familiar to us all, but we may note that they are for the most part of a physical nature, being due not so much to pigment as to external markings, which produce iridescence. As to the evolution of the eye-like markings, which occur in varying degrees of perfection, we have on the one hand to recognise with Darwin the more beautifully decorated males are selected by their mates, and on the other hand that we do not know to what precise conditions of feather growth the marvellous beauty is due. The Javan peafowl is said to be even handsomer than the familiar species. Its crest, head, and neck are rich green, the breast bluish-green margined with gold, the back bright copper-colour barred with green and light brown, and the upper tail-coverts rich green with gold and copper-colour reflections. White or pied peacocks occasionally occur as sports, and yet more remarkable is the appanage of the female, and this seems to have arisen quite abruptly.

The peacock seems to have been well known in Greece after Alexander's Indian expedition, but it was known in Judaea even in the time of Solomon. From Greece it spread to Rome and gradually westwards. In many different ways it has found a place in human life and fancy; it was the bird of Juno to the Greeks and Romans, and emblematic of a glor-
fied body to the early Christians; its feathers have adorned many a throne and shrine, and the perverted luxury of the later Roman empire made an entree of the tongues or brains. The eggs and the young are edible, but domesticated peacocks are kept almost solely for their beauty's sake, and that as often as they are not got to do mischief both in garden and poultry-yard.

**Peacock.** Thomas Love, satirist, was born at Weymouth on 18th October 1785, the only child of a London merchant, who died three years afterwards. His boyhood was passed at Chertsey, and for four years he was sent to a private school on Englefield Green, but from thirteen he was self-educated, growing up an accomplished scholar. The chief events of his uneventful life were the loss of his first love (1808); his under-secretaryship to Sir Home Popham on a warship at Finishing (1809-10); his close friendship with Shelley, whom he first met in Wales in 1812, during one of his many walking tours; his employment from 1819 to 1856 in the office of the East India Company, as clerk, correspondent, and chief examiner; his marriage to Mrs. Gryll, the daughter of the Carew Baronet, in 1839; and the death of his sons and daughters, and his own, which occurred in 1852 after twenty-six years of ill-health; and the important part he bore in the introduction of iron steamships to Eastern waters (1832-40). In 1823 he had taken a cottage at Halliford on the Thames, where he died, aged eighty, on 23d January 1866.

Peacock's literary activity extended over more than half a century. Of his half-dozen booklets of verse, published between 1804 and 1837, the best, *Rhododaphne*, offers nothing so good as some of the gay lyrics scattered throughout his seven 'novels'—*Headlong Hall* (1816), *Metempsychon* (1817), *Nightmare Abbey* (1818; its hero is Shelley), *Maid Marian* (1822), *The Misfortunes of Elphin* (1829), *Crochet Castle* (1831), and *Gryll Grange* (1860). And these 'novels' are interesting chiefly as a study of character—the author's own. A melodramatic pagan of the 18th century, egoistic, profligate, such was Thomas Love Peacock, and in Thomas Love Peacock we have the Alpha and Omega of his writings. They mirror his likings (for nature, music, the classics, madeira, and good living generally), and his stronger, if exaggerated, dislikes (for field-sports, reviewers, political economy, all things Scotch and American, and, above all, Lord Brougham). They leave on one the impression that the little he 'dil not know was to his mind not worth knowing, that because, for example, he had not been at a university and was not religious, therefore Oxbridge and heaven were beyond his microcosm. They may still find admirers in the cultured few, but the stilly wit and erudition of their dialogues can never touch the great heart of the people. They are—true though it sound—"caviare to the general."

See Sir Henry Cole's collected edition of Peacock's works, with a preface by Lord Houghton and a memoir by his granddaughter (5 vols. 1875); Dr. Garnett's edition (10 vols. 1860), and an article by Sneadie in *The Edinburgh Review* for July 1875, and one by Mr Gosse in *col. iv. of Ward's English Poets* (2d ed. 1883).

**Peacock-stone.** The name under which the dry cartilaginous ligaments of some large bony-brained molluscs, as the pearl-oyster, have been sold by jewellers.

**Pea-crab** (*Pinnothetes*). See CRAB, COMMENSALISM.

**Pea-pod.** The fluffy billy district of north-west Derbyshire, having Castleton for its capital, 10 miles N. of Buxton. Measuring some 30 by 22 miles, it is watered by the Dove, Derwent, and Wye, and culminates in Kindercaust (2092 feet), other eminences being Axe Edge (1810 feet) and Main Tor (1710). The Peak Cavern or Devil's Hole near Castleton penetrates 750 yards; and crowning a rock above the village is Peveril Castle, so named from its first lord, a bastard of William the Conqueror. The wonders of the Peak were celebrated by Thomas Holme (1666) and Charles Cotton (1683). Recent works are by Cronin (1862; new ed. 1889), Bradbury (1879), L. J. Jennings (1880), and Leyland (1881), besides others cited at DERBYSHIRE.

**Pear-nut.** See GROUND-NUT.

**Pear.** The pear (Pyrus communis), a member of the Pomaceae, a sub-order of Rosacea, is a tree very largely cultivated for the sake of its fruit, which contests with that of the peach the first place in the list of the British Fruits and probably exceeds it in endurability. The pear is a native of Europe and the more temperate parts of Asia, and is still found wild in Britain, but in that state is of lesser girth and stature, with thorny branches and small harsh fruit, and jagged and sometimes pinnate leaves. A wilder variety, which the trees usually grow to 60 feet, with a trunk or even more in diameter, while the thorns disappear, though in some kinds they linger for years after grafting; the leaves are simple, ovate, serrate, or crenate, and sometimes almost entire; glabrous on the upper surface, sometimes tomentose on the under side while young; the flowers are in corymbs of five to eight or nine or even more, each bloom having five petals, generally white, though in some varieties toned or striped with pink, differing also in size and shape according to variety. The fruits are numerous, and the styles distinct, generally five in number and enclosed within the calyx-tube. With the growth of the fruit the ovaries become united, and form what is called the core, consisting usually of five cells, and each cell has one or two seeds or pips, which in many of the best kinds are imperfect. The fleshy mass which is formed around these constitutes what we call the fruit, differing greatly in form, size, and substance, according to variety, health, climate, and other influences. But the normal form of the pear as seen when grown as one of description, is cylinndrical, long, and tapering from the stalk to the part just above the eye, where the diameter is greatest.

The pear-tree is grown upon divers stocks, as well as in many shapes and manners, by English gardeners, and is as it were fixed to stock—by other treatment—gardeners use either pear or quince, (a) the pear (which is called the free stock) being raised for that purpose from seed or otherwise, and grafted when strong enough, or budded, with the sort required. This is the way to obtain large trees, lusty and enduring, but both to give fruit until they have found long experience. *Inseccum quidem, sed leta et fortia surgit.* Whence the old distich—"The man who plants pears is a-planting for his heirs. This has told much against the liberal sale of pears, but there is no mischief with the race of provers is exaggerative. (b) The quince-stock, shallow-rooted, less vigorous in habit, and of briefer date. Upon this stock the pear, when congenital to it, begins to fruit even in the second or third year of working, grows large if the more beautiful, and sometimes better produce than it could afford upon its closer kindred, but does not grow to the bulk or stature which nature intended for it. It is a mistake, however, to suppose that the tree so wrought is cut short of life, unless of a stature too tall for the piazza, as some of the more pears have always done. Other pears, indeed the great majority, thrive upon the quince for from ten to twenty years; and some kinds there are which show every sign as yet of a life as long and almost
as large as they could have attained without trans-
migration. (c) Other stocks whereupon the pear
will grow are the Hawthorn, the Sorbus, the CYD-
amon japonicus, and several other members of the
pyric race. Some kinds of pear will do well on
some of these. But in spite of all local and para-
doxical flourish, the stern fact remains that the
success is fitful, comparatively brief, and scarce-
ly worth the trouble.

(2) The shape and manner of growth are also
much varied. In the northern counties of Great
Britain and the bleaker portions of the south the pear—
unless it be of an early kind—will not ripen well
without the aid of glass or the shelter and warmth of
a garden wall. It is not largely grown under
glass as yet, and for many good reasons, though
very fine specimens are thus obtained. And as a
wall-tree it is to be found in almost all fruit-
gardens, and much of the finest fruit is thus pro-
duced. There are four modes of training now
chiefly in vogue—viz., the old horizontal, the fan-
shaped, the rectangular fork (with from two to
twenty branches), and the cordons, diagonal or
horizontal, single, double, or treble, &c., and some-
times tortised into spirals. But, wherever the
pear will ripen without the absorbed and reflected
heat of a wall, the simplest and cheapest form of
growth is that which our nurserymen call the
dwarf. This is very generally accepted in the
North—or, with some few varieties which spurn that
form, the less compact outline of the bush. Some
difficulty is needed at least twice a year to keep
any of these in discipline.

(3) The varieties of pears are almost countless,
as are those of apples, and nine-tenths are unworthy
of the census. If this was so in the time of Virgil, we
must not be surprised at the catalogue now. No
year, however barren, lacks new kinds on paper,
which are to supersede all previous issue. But the
historical fact survives that pears were as we,
worth eating in the days of our ancestors as they
are now, and that not more than some half-dozen
of the hundreds introduced within the last forty
years have earned their too obsequious welcome.
And of this select band there are only three that
deserve a place for ever—viz., the Conference
(terms the crown and the criterion); Borsœt
superbus, a noble satisfaction; and Josephine de
Malinche, an exquisite refinement. Also there is a
grand pear of English origin, the Pitmaaton Duchesse,
not of the finest quality, but good enough to be
allowed by those who are tired of the grand.
There will add, according to liking or locality, the best
of the older kinds that have stood the test of
generations, such as Jurgenselle, Williams' Don
Christian, Louise Bourne, Marie Louise, Knight's
Monarch, and Fondante d'Antoinette, and some ten
or twelve others, preferring merit to magnitude,
and bearing in mind the simple truth, though a
stumbling-block to the million, that all fruit is
better without wall or glass, when it can be so
brought to perfection.

In the United States the favourite variety is the
Bartlett, which is exported in large quantities.
The Seckel is a smaller fruit, but of a more delicat-
flavoured. The states in which the pear is
chiefly grown are California, Georgia, and Florida.

See Bogg's Fruit Manual; The Orchardist, by John
Smith; the Conference at Chiswick, and the
Pomological Dictionary of ANDREW.

PEAR. PIMLY. See PRICKLY PEAR.

Pear, a peculiar progeny of certain marine and
fresh-water mollusces. Most shell-bearing mol-
lusces are provided with a secretion in which
they line their shells, and give to the otherwise harsh
granular material of which the shell is formed a
beautiful smoothly surface, which prevents any
unpleasant friction upon the tender body of the
animal. This secretion is laid in extremely thin
semi-transparent films, which, in consequence of
such an arrangement, have generally a beautiful
and decorative appearance. But, in some cases, suf-

icient thickness to be cut into useful and orna-
tmental articles. The material itself in its hardened
condition is called naure by zoologists, and by dealers
mother of pearl. Besides the pearl lining of the
shells, detached and generally spherical or
dumb-bell shaped, that pearls are often found in
opening the shells, and there is great reason to
suppose that these are the result of accidental
causes, such as the intrusion of a grain of sand, or
the frustule of one of those minute siliceous vegetables
known as diatoms, or a minute parasite, or even one
of the ova of the pearl-oyster itself, which, by irri-
tating the tender body of the animal, obliges it in
self-defence to cover the cause of offence, which
it has no power to remove. Around this foreign
body thin layers of naure are deposited one after
another, like the successive layers of an onion,
until the object is surrounded sufficiently to
form a pearl. The natural pearl is formed. The pearl is formed of concent-
tric layers of carbonate of lime of extreme tenuity,
but of the same general character as those compos-
ing the shell.

The most famous pearls are those of the East;
these accounts obtained theirs mainly from Ceylon
(Tambrapura) and the Persian Gulf, whence none of
the best pearls still come. Other pearl-fishers
are in the Sulu Archipelago, off New Guinea, off
some parts of the Australian coast, and amongst
some of the Polynesian islands. In the Persian
Gulf the most important pearl-yielding mollusc is the
Arcaia (M. Acanthes) fucita. It is specially
fished for pearls, and yields them in greatest
number and of the finest kinds. It has a much
smaller shell than the species which has been
hitherto known, Paliis, Aconchus (M.)
margaritifera. This last and another
species (A. macroleopida) are also extensively fished
for in the gulf; but, though pearls are found in both,
and they are much more valuable for their shells
than for the pearls they sometimes contain. Like
A. margaritifera, the A. macroleopida has also
a large shell. It is all three species, living about
the Island of Bahrain on the west side of the
gulf. The centre of the trade is the port of
Lingah, but all the pearls that come hither are called
Bambay pearls. A steamer with a diver and
an assistant, and a large boat, is sent out by an English
firm of merchants in 1884. These people gather
and pearls in the deeper water on the east side of
the gulf, but the experiment did not succeed.

Of the Ceylon pearl-fishery, which, like the
Indian ones on the Madras side of the Strait of
Masttir, is under government supervision, and is
only allowed at irregular intervals, some account
is given at Ceylon, Vol. III. p. 78. The method
of fishing may be thus described. The season
of the fishery, when permitted, lasts from four
to six weeks. For each diver there is provided
dive-time, weighing about forty lb., which is
fastened to the end of a rope long enough to reach
the bottom, and having a loop made for the man's
foot. To each boat there is usually allotted a
crew of thirteen men and ten divers, five of whom
are descending whilst the others are resting.
This work goes on very rapidly; for, after thoroughly
reading the stories of divers who come down below for
four minutes (see Diving), the best divers cannot, as
a rule, remain longer than eighty seconds below, and
few are able to exceed sixty. The greatest depth
they descend is thirteen fathoms, and the usual
depth about nine fathoms. When the diver gives
the signal by pulling the rope he is quickly hauled
up with his net and its contents. Probably the
rarity of accidents from sharks, usually so abundant in tropical seas, is to be attributed to the bale and to the excitement of the waters during the fishery frightening away those dreaded creatures. The diving is sometimes fixed ages, others agree for one-fourth of the product given. When a fresh catch of oysters has been obtained it returns to shore, and the cargo, sometimes amounting to 20,000 or 30,000, is landed and piled on the shore to die and putrefy, in order that the pearls may be easily found. In Calpey, one of the thinner layers of this delicate shell has brought up 11 million oysters, which sold for 2s. per 1000, the government receiving £10,000 and the divers £200. When the animals in the shells are sufficiently decomposed the washing commences, and great care is taken to watch for the loose pearls, which are always by far the most valuable; the shells are then examined, and if any attached pearls are seen they are handed over to the clippers, who, with pinchers or hammer, skillfully remove them. Such pearls are only used for setting; whilst the loose ones, being usually small, are valued and strung, and can be used for necklaces, &c.

The pearls vary much in size; those as large as a pea, and of good colour and form, are the best, except unusually large specimens, which rarely occur. The largest pearl on record is said to be the pearl in Mr Beresford Hope's collection at South Kensington, which measures two inches in length, and four in circumference, and weighs 1800 grains. The smaller ones are sorted into sizes, the very smallest being called seed-pearls. A number of these pearls which are last are sent to China, where they are said to be calcined and used in Chinese pharmacy. Amongst the Romans the pearl was a great favourite, and enormous prices were paid for fine ones. The single pearl which Cleopatra is said to have dissolved and swallowed was valued at £80,729; and one of the same value was cut into two pieces for earrings for the statue of Venus in the Pantheon at Rome.

The finest pearls are found within the mantle of the mollusc, close to the lips of the shell, or in the soft part of the oyster near the hinge of the shell; the worst pearls are those found within the close, coarse fibres of the adductor muscle. At intervals they are found loose in the shell outside the body of the oyster, and may when large get washed out of the shell and thus be lost. Lastly, pearls are often found half in, and half out of, the soft shell, having in some cases escaped from the soft tissues.

It is notable that the adherent pearls occur almost invariably in the flat or lower valve; occasionally, it is true, they are found embedded in the rounded or upper valve, but in such cases it is observed that the shell has been found lying at the bottom in the reverse position. The pearls found embedded in or under the ‘muscular impression’ are always small, irregular, and worthless, similar to those found embedded in the adductor muscle itself. Pearls are found in every variety of size, and the consecutive layers vary in brightness, colour, and perfection. The most highly prized pearls are quite spherical, and it is evident from their shape that these must have been formed free in the mantle or in the soft tissues of the mollusc, and not in the shell, which has been observed to be the case in many cases of pearls which are found in the soft tissues of the shell. The commonest defects caused apparently by the contact of new foreign substances, organic or inorganic, such as a grit or film of weed; and in some cases it requires a number of layers to completely hide these defects. Thus every new layer secreted changes the position of the pearl that has been formed from the shell presents a hemispherical surface, it is sometimes called a ‘perle bouteon’; such a pearl is flat on one side, and rounded or convex on the other. If a solid pearl has an irregular shape, having grown over a rough object, it is known as a baroque pearl. Sometimes warty pearls are hollow, and pass under the name of ‘coq de pere.’

Pearl-oysters frequently renovate their shells, and are in the habit of burying such intruders as they cannot otherwise digest. Smaller shells, wood, and especially layers of weed are found thus embedded in shells forming unnatural excrescences on the surface. These protuberances are gradually removed by the oyster secreting its shell over the top of them; thus the figures of Buddha lying embedded at equal distances apart, on the upper portion of the shell near the lips, but not so deeply buried as to be hidden. These are produced artificially in China; "the little figures are shaped carefully below the mantle of the oyster, and the process of deposition covers them with nacre. The value of a pearl depends upon its size, shape, colour, brightness, and freedom from defects. The most valuable pearls at the present time are those which are perfectly round; the button-shaped ranks next, and then comes the drop or pear-shaped pearl. Perfectly round pearls over 25 grains in weight are extremely scarce, and secure high prices. They are greatly sought after to form the centre of necklaces, and large pearls of this character are safe and very profitable investments. The varying tints and colours of pearls are less difficult to understand than some of their eccentricities of growth. The changing condition of the sea, both as regards purity and temperature, the health of the oyster, accidents, such as the discharge of the inky fluid of the cuttle-fish in the neighbourhood of the oyster, all will probably affect the colours of the successive growth-periods of the pearl. Pearls, when of extraordinary beauty, size, and brilliancy, will sell for sums which appear extravagant.

The chemical composition of the pearl is carbonic of lime associated with a small proportion of organic matter. It is easily affected by acids and feth gases, and may be calcined by exposure to heat. Its sp. gr. is 2.2 to 2.7. Three varieties of pearls being examined, British, Australian, and Singhalese, the qualitative analyses showed that they all had an identical composition, and that they consisted solely of water, organic matter, and calcium carbonate. There was a total absence of inorganic part of pearls must of course be obtained. The most important marine pearl-fishery on the American continent is that of Lower California, the central point being at La Paz. The largest and finest black pearls which come into the market are the specialty of these fisheries. In Australian waters pearls are fished on the coast of West Australia and of Queensland, and in Torres Strait. River-pearls are produced by fresh-water mussels in Scotland, and on the rivers of Poland, Germany, Canada, and the United States. British pearls are spoken of by Tacitus and Pliny; and in the end of the 17th century the Scottish pearl-industry was of some importance. The Spey, Tay, South Esk, Doon, Don, Ythan, and Forth have
all yielded pearls, and a temporary revival of the industry took place in 1860 and succeeding years. In the United States the chief river-pearl fishery is in the Little Miami, in Ohio; but China is the greatest producer of the valuable river pearls.

False pearls are made by blowing very thin beads or balls of glass, and pouring into them a mixture of liquid ammonia and the white matter from the scales of the blank, and sometimes of the roach and silce. The scales of the lower part of the fish are very carefully washed and put to soak in water, when the pearly film falls off and forms a sediment at the bottom of the vessel, which is removed and placed in liquid ammonia for future use. This pearl mixture, when of the best quality, is very costly, being as much as £4 or £5 per oar. For use it is diluted with ammonia, and injected into the glass beads, so as to thinly coat them inside; afterwards the better kinds have melted white wax or mucilage of gum-arabic poured in, which renders them much more durable. In this way are produced imitations of the finest oriental pearls, such as only the practiced eye can detect. The art of giving the irregular forms of large pearls to the glass bulbs increases the resemblance; and the glassy appearance caused by the exterior glass coating is removed by exposing it for a short period to the action of the vapour of hydrochloric acid.

Roman pearls are lighter, as they have the coating of pearly matter on the outside.

See Streeter’s Pearls and Pearlaring Life (1880), and G. F. Kurn’s Gems and Precious Stones of North America (New York, 1890).

THE HISTORICAL PEARL. The shells of several species of molluscan animals are popularly known as mother of pearl, those, for instance, of Avicula macroptera and of some species of Halistis. To the shells, however, of Avicula (Melagrarium) margaritifera the term mother of pearl is properly applied.

The species has a wide distribution in tropical seas. Macassar mother of pearl, from white-edged shells, is the most highly prized; the Manilla yellow-edged shells are not much inferior; and the shells from some parts of Australia are also of a high quality, but those from Sydney and Auckland are of a gray texture. The poorest shells come from Panama. By far the greatest supply of mother of pearl is now got from the north and northwest of Australia, but large quantities also are obtained from the Straits Settlements, the Persian Gulf, and the islands of the Pacific. The total annual value of what is imported into England is between £250,000 and £290,000, but much of this is sent to continental Europe.

The shell of the large pearl-oyster is thick, of slow growth, and sometimes measures nearly a foot across. Until the Australian fisheries were commenced about 1865 the supply of mother of pearl was diminishing, while the demand for it was and is constantly increasing. In France about 4000 and in Austria some 8000 persons are employed in working this substance for parts of fine furniture, inlaid work, fans, buttons, &c. In England it is also largely made into buttons, cutlery handles, and ornaments for papier-mâché boxes, trays, &c.; in China and Japan lacquer work has long been decorated with mother of pearl. In Cashmere it is used for the inscriptions on gravestones; and fishhooks are made of it in the South Sea Islands.

See editions of the Exposition on the Creed by Burton (1853); of the Minor Theological Works, by Churton (1844).

Peary, Robert. American naval captain, has undertaken five adventurous journeys along the Greenland coast (1866-99). He further proved Greenland an island, defined the outline of the N.E. corner, and brought back the enormous meteorite reported by Ross in 1818. See his Northwest over the Great Ice (1898), and other books by Keely and Davis (1892), Hedin (1893), Mrs Peary (who twice accompanied her husband), and Astrup (trans. 1898).
